An incomplete type and a forward reference generally mean the same thing.

In C++ using == to compare one array to another is permitted (if meaningless).

You must use an integral constant or literal to specify the size of a built-in C++ array.

The reinterpret_cast instruction changes way that a pointer's indirect value is interpreted.

If p is a pointer to a structure, and the structure contains a data member x, you can access the data member by using the notation: (*p).x

C++ arrays have no support for bound-checking.

In C++ assigning one array to another is illegal

The allocated size of a built-in C++ array cannot be changed during runtime.

The size of the array is not stored along with its elements.

If img is a pointer to the first byte in an image loaded into memory, Pixel is a structure as defined in your textbook, you can create a Pixel pointer pointing to the image by writing:

Pixel **p = reinterpret_cast<Pixel** >(img);

The subscripts of a C++ array range from 0 to the array size - 1.

C++ arrays have no built-in functions for inserting and deleting.

A forward reference can be used when you want to use a pointer to a structure as a data member without first defining the entire structure.

The elements of a C++ array created in a function are allocated on the stack.

The elements of a C++ array created outside of a function are allocated in the static-storage area.

The elements of a C++ string array with no explicit initialization, created in a function will be set to the empty string.

Explicitly initializing an array like this: int $a[3] = \{1, 2, 3\}$; requires the size to be the same or larger than the number of elements supplied.

In C++ printing an array name prints the address of the first element in the array.

In C++ there is no separate array variable. The array name is a symbolic representation of the address of the first element in the array.

In C++ initializing an array with the contents of another is illegal. $\label{eq:contents}$

C++ arrays produce undefined results if you access an element outside the array.

Explicitly initializing an array like this: int a [] = {1, 2, 3}; works in all versions of C++.

True

You may use any kind of integral variable to specify the size of a built-in C++ array. The elements of a C++ string array with no explicit initialization, created in a function will be set to null. Explicitly initializing an array like this: int a[3] = $\{1, 2, 3\}$; requires the size to be the same or smaller than the number of elements supplied. In C++ using == to compare one array to another is illegal. The allocated size of a built-in C++ array may be changed during runtime If img is a pointer to the first byte in an image loaded into memory, Pixel is a structure as defined in your textbook, you can create a Pixel pointer pointing to the image by writing: Pixel **p = static_cast<Pixel** >(img); The reinterpret_cast instruction produces a temporary value by converting its argument. In C++ initializing an array with the contents of another is permitted. C++ arrays use bound-checking when you access their elements with the at() The elements of a C^{++} array created in a function are allocated on the heap. In C++ assigning one array to another is permitted. C++ arrays throw an out_of_bounds exception if you access an element outside the array. In C++ an array variable and the array elements are separate. The array variable contains the address of the first element in the array. In C++ printing an array name prints the value of the first element in the array. The elements of a C++ int array with no explicit initialization, created in a function will be set to zero. C++ arrays can be allocated with a size of 0. The static_cast instruction changes way that a pointer's indirect value is interpreted. The size of the array is stored along with its elements. The allocated size of a built-in C++ array may be changed during runtime A forward reference can be used when you want to use a structure as a data member without first defining the entire structure. The elements of a C++ array created outside of a function are allocated on the stack. If p is a pointer to a structure, and the structure contains a data member \boldsymbol{x} , you can access the data member by using the notation: p-xC++ arrays offer built-in member functions for inserting and deleting. Explicitly initializing an array like this: int a $[= \{1, 2, 3\};$ only works in C++ 11. Unix and C Ken Thomson and Dennis Ritchie Fortran John Backus Simula O. Dahl & K. Nygaard Berkeley Systems Distribution Unix Bill Joy C++ Bjarne Stroustrop Richard Stallman GNU, GCC and Free Software Code is written in machine (and assembly) language for a specific processor; thus it native code machine language is non-portable or machine dependent. More efficient than Java or Python Which of these statements apply to C++? Produces native code that runs on the CPU Compiles to native code Compiler Converts processed source code to object code.

Combines object modules to produce an executable.	Linker
Provides instructions for building your program.	Make
Reads an executable image on disk and starts it running.	Loader
Performs text substitution on your source code.	Preprocessor
What is wrong with this IPO code fragment?	Input occurs after output
cout << "Name: ";	
string name;	
cout << "Hello, " << name << endl;	
cin >> name;	
>>	Extraction or input operator
cout	Analogous to Java's System.out
«	Insertion or output operator
cin	Similar to Java's Scanner objects
\n	Escape character
endl	Stream manipulator
What kind of error is this?	A syntax error
error: expected ';' after expression	
What is the problem here?	You filled out the STUDENT variable incorrectly
You have submitted another student's completion code	

What is the problem here?	The programmer is in the wrong directory.
make: *** No targets specified and no makefile found. Stop.	
The makeful for LOV is mission	
The makefile for h04 is missing	Compiles, runs and returns 0 to the O/S

share an operand?
                ___ of an operator determines the number of items it operates on?
  The
                                                                                            arity
                          What prints?
                                                                                             .666667
                          int main()
                          {
                          cout << fixed << 2.0 / 3.0 << endl;
                          }
                                                                                             6.66667e-02
                             What prints?
                            int main()
                             cout << 2000 / 3.0 << endl;
                            }
```

```
int main()
            cout << fixed << 2000 / 3.0 << endl;
        What prints?
                                                                                6.67e02
        int main()
        cout << setprecision(2) << 2000 / 3.0 << endl;
    What prints?
                                                                                666.67
    int main()
    cout << fixed << setprecision(2) << 2000 / 3.0 << endl;
                                                                                15UL
    Match each item with the correct statement below.
                                                                                12
    unsigned long
                                                                                15ULL
    signed int
    unsigned long long
                                                                                15U
    unsigned int
     signed long
                                                                                3L
     signed long long
                                                                                15LL
The standard input object; analogous to a Scanner in Java
                                                                                cin
Modifies and manipulates data to produce information
                                                                                processing
The header used to include the standard streams
                                                                                iostream
A single entity that bundles data and instructions
                                                                                object
Displays the results of calculations
                                                                                output
cout stands for ____
                                                                                character output
The standard output object; analogous to System.out in Java
                                                                                cout
The output or insertion operator
endl is a ___
                                                                                stream manipulator
Retrieves data and stores it in variables
                                                                                input
C++ uses an _____ library for input and output.
                                                                                object-oriented
Text enclosed in double quotes
                                                                                string
The header used for formatting real numbers
                                                                                iomanip
Asking an object to perform certain operations
                                                                                sending a message
              Literals like 3 and 7 are always:
                                                                                B O T H : rvalue
              On line 3, b is:
              int a = 3; // 1
              int a = 7; // 2
              a = b; // 3
                    On line 2, b is:
                                                                                A non-modifiable lvalue
                    int main()
                    a = 3; // 1
                    const int b = 7; // 2
                    a = b; // 3
                                                                              >>
        Which operator is the extraction operator?
         Which operator is the insertion operator?
                                                                               <<
      What header is needed to use the string type?
                                                                                <string>
        What header is needed to use cin and cout?
                                                                                <iostream>
       What header is needed for output formatting?
                                                                                <iomanip>
     What header is needed to use the sqrt() function?
                                                                                <cmath>
```

```
int n = 12;
                            cout << n/3 << endl; // 1
                            cout << n/7 << endl; // 2
                            cout << n % 3 << endl; // 3
                            cout << n % 7 << endl; // 4
                                                                                            2425
                          What is printed when this runs?
                         int sum = 22;
                         sum +=2;
                         cout << sum++; // sum = sum + 4
                         cout << sum << endl;
                  What is the output of the following program?
                                                                                            4
                  int value = 3;
                   value++;
                   cout << value << endl;
                                                                                           2
                         Which line or lines are illegal?
                         /1/ int a, b;
                         /2/ a = 3;
                         int main()
                         /3/b = 4;
                         /\textbf{4}/ cout << a << ", " << b << endl ;
                         }
                          Which line or lines are illegal?
                                                                                            None of these
                          int a;
                          int b = 3;
                          int main()
                          a = 4;
                          literal
Symbols which directly represent a value (literal)
                                                                                            associativity
Determines the direction of operations for operators at the same level (associativity)
Describes how many operands an operator requires(arity)
                                                                                            arity
Operators that require a single data value (unary)
                                                                                            unary
Symbol which indicates a value (operand)
                                                                                            operand
Determines how tightly operators bind to operands
                                                                                            precedence
(precedence)
Any combination of operators and operands which yields a value
                                                                                            expression
(expression)
A symbol that can be used to produce a value at runtime
(function call)
                                                                                            function call
Symbol which indicates an operation
(operator)
                                                                                            operator
A storage location containing a value
(variable)
                                                                                            variable
Operators that require two data values(binary)
                                                                                            binary
                Types such as classes, structures and enumerations
                                                                                            user-defined types
                Types such as pointers, arrays and references
                                                                                            derived types
                Built-in types, such as int and double
                                                                                            primitive types
                The "kind" of a variable
                                                                                            data type
                Read a value and store it in a variable
                                                                                            input
                Types such as string and vector
                                                                                            library types
                Which of these five concepts are illustrated here?
                                                                                            Declaration
                                                                                            Definition
                int main()
                int a;
                 }
```

CTOTI	Study
int main()	
extern int a; }	
Which of these five concepts are illustrated here?	Assignment
int main()	Declaration
{ extern int a;	
a = 3;	
,	1
Associates a name with a type	declare
Read a value and store it in a varaible	input
Copy a new value into an existing variable	assign
Allocates space for a variable	define
Provides a starting value when a variable is created	initialize
A named storage area that holds a value	variable
What is true about identifiers in C++?	They may contain an underscore
As an application programmer, which of the following names for local variables are both legal and recommended for stylistic reasons.	_ (single underscore)
both legat and recommended for stylistic reasons.	CamelCase
	cout
As an application programmer, which of the following names for local variables are	2cool CamelCase
legal (even if they are unwise from a stylistic perspective).	U2
	integer
Which manipulator is used to ensure that large numbers appear using regular decimal notation?	fixed
Which manipulator is used to change the padding character used in a column like: 0045?	setfill()
Which manipulator(s) is/are used to make sure the value 2.0/3 prints like this: 0.677?	fixed setprecision()
Which manipulator(s) is/are used to make sure the number 45 prints like this: 0045?	setfill() setw()
Assume int x, y, z;	y += z;
Shorthand assignment	X++;
Post increment	X = Z++ - ++Z;
Undefined behavior	double a = y;
Widening conversion	z;
Pre decrement	x = y = z = 10;
Chained assignment	z = 3.15;
Narrowing conversion	auto v = x * 2.3;
Mixed-type expression	<u> </u>
Which of the following variables have the value 0?	global
int global; int main	
{	
string localStr; double localDouble;	
Which of the following unsighted have an analytic to the	I Jacol Double
Which of the following variables have an undefined value?	localDouble
int global; int main	
{	
string localStr; double localDouble;	
}	

int global; int main	
{	
string localStr; double localDouble;	
}	1
The variable ASSIGNMENT from your homework has been	declared
The variable STUDENT from your homework has been	initialized defined declared
This code is legal, compiles and is well defined. Which line(s) contain an assignment?	4
int a = 5; // 1	
a == 5; // 2 int b = 6; // 3	
a ={b}; // 4 auto c = a == b; // 5	
This code is legal, compiles and is well defined. Which line(s) contain comparison?	2
int a = 5; // 1	5
a == 5; // 2 int b = 6; // 3	
a ={b}; // 4 auto c = a == b; // 5	
This code is legal, compiles and is well defined. Which line(s) contain initialization?	<u>. </u>
The code is togal complete and to not domest. This is not contain made and the not domest.	3 5
int a = 5; // 1 a == 5; // 2	
int b = 6; // 3	
a ={b}; // 4 auto c = a == b; // 5	
This code is legal, compiles and is well defined. Which line(s) contain an input statement?	None of these
int a = 5; // 1 a == 5; // 2	
int b = 6; // 3 a ={b}; // 4	
auto c = a == b; // 5	
The + arithmetic operator is a(n) operator	binary
The - operator is a(n) operator	unary binary
The ++ arithmetic operator is a(n) operator	side effect unary
A set of bits interpreted according to its type	Value
x in the expression x = 3;	lvalue
x in the expression y = x;	rvalue
Uniform or list initialization	int c{5};
Legacy or assignment initialization	int a = 0;
Direct initialization	int b(3);
const double PI = 3.14159;	non-modifiable value
narrowing conversion	int e(3.5);
Assume that the user enters: Steve 60 3.5 What value is stored in gpa?	3.5
string name;

Strings in C++ are mutable.	True
String in C++ are immutable	False
In C++ you can compare strings using all of the relational operators.	True
In C++ you cannot use the relational or equality operators with strings.	False
Assuming str is a string object, this syntax is legal in both Java and C++. Does this code work correctly in both languages?	False
if (str == "quit")	
In C++ you can concatenate string objects using the + or += operators.	True
Assuming str is a string object, is this syntax legal in both Java and C++?	True
if (str == "quit") Assuming str is a string object does this correctly test if str consists of the characters "quit" in C++?	True
if (str == "quit")	
Assuming lastName is a string object, does this work as expected in C++?	True
if (lastName <= "Gilbert")	
fruitful function	A function that calculates and returns a value
body	A block containing statements that implement the function's actions.
function	A named block of code that carries out an action or calculates a value.
prototype	Another name for a function declaration
parameters	Variables defined along with the function to receive input
calling	Executing, running or invoking the function
procedure	A function that carries out an action instead of calculating a value.
return statement	Produces a value when the function is invoked
defining	Specifying the calculation or actions that occur when the function is used
declaring	Specifying the function name, type and parameter types.
arguments	Values passed to the function when it is invoked

Which control structure is best equipped to handle an on or off condition?		if-else statements
Which control structure is best equipped to handle numeric selections made from a menu?		the switch statement
Which control structure is best equipped to handle processing for a group of radio buttons?		sequential if statements
Which control structure is best equipped to handle processing for income taxes?	I	nested if statements
Which control structure is best equipped to set a variable to one or two possible values?		the conditional operator
This code illustrates the idiom.		alternative action
if (n % 2 == 1) cout << "Odd" << endl; else cout << "Even" << endl;		
This code illustrates the idiom.		guarded action
if (n % 2 == 1) cout << "Odd" << endl;		
This code illustrates the idiom.		multiple selection
auto n = 3; if (n % 2 == 1) n = -n;		
else if (n < 0) n++; else if (n % 2 = 0) n;		
else n = 0;	 -	
This code illustrates the idiom.		Independent if statements
auto n = 3; if (n % 2 == 1) n = -n;		
if (n < 0) n++; if (n % 2 = 0) n;		
This code illustrates the idiom.		None of these are correct
auto n = 3; else if (n % 2 == 1) n = -n;		
else if (n < 0) n++; else if (n % 2 = 0) n;		
else n = 0;		
The C++ string class is defined in the header:		<string></string>
You can find the length of a string str using str.size(). In C++, size() is called:		a member function
Which operator is used to see if all of a set of conditions is true?		logical and
Which operator is used to see if any of a set of conditions is true?		logical or
If a is false, which expressions need not be evaluated?		b
if (a && b c && d e)		
If a and c are both false, which expressions need not be evaluated?		b, d
if (a && b c && d e)		
If a and b are true, which expressions need not be evaluated?		c, d, e
if (a && b c && d e)		
Produces the empty string	١	string s1; (choice A)
Implicitly converts a character array to a string object	l	string s2 = "hello"; (choice B)
Explicitly converts a character array to a string object		string s3{"world"}; (choice C)
Produces a string from multiple copies of a single character	l	string s4(20, '-'); (choice D)
Produces a string that may contain quotes or backslashes	l	string s5(R"("bob")"); (choice E)
Needed to use the C++ string type	I	#include <string> (choice F)</string>
Reads one word or token from standard input	I	cin >> s1; (choice G)
Reads one line of text from standard input	I	getline(cin, s2); (choice H)

C+3+I	Study
cout << "What's your name: "; string name; cin >> name; cout <<"Howdy " + name + "!"; What is the output? auto x = 40; if (x <= 40) cout << "F"; if (x <= 75) cout << "C"; if (x <= 90) cout << "B";	FCB
cout << endl; In C++, what is true about concatenating string literals (character arrays)?	you do it by separating the string literals with white space
In C++, the statement string s{3, 'X'};	creates a string variable of size 3, filled with 'X'
In C++, the statement string s{"world"};	creates a string variable explicitly initialized with the character array "world"
In C++, the statement string s = "world";	creates a string variable implicitly initialized with the character array "world"
In C++, what keyword is used for type inference?	auto
In C++, characters of the type char:	Can be preceded by signed or unsigned for use as small integers Generally use 8 bits of storage. Use the ASCII character set Are defined for the first 127 characters
In C++, characters of type char:	Can be preceded by signed or unsigned for use as small integers Generally use 8 bits of storage. Use the ASCII character set Are defined for the first 127 characters
In C++, what is true about the += operator operating on string objects	You may concatenate creates a string variable to a string object You may concatenate a string literal (character array) to a string object You may concatenate a char literal to a string object You may concatenate a char variable to a string object
The code shown here: auto n = 3; if (n = 0) cout << "n is 0" << endl; else	Executes the false branch Displays "n is 0" Contains an embedded assignment
cout << "n is " << n << endl;	
Assume that name is a string object. Which of these expressions are legal?	name += 'X' name < "bob" name == "sally" name += "fred"
What is true about string::size_type?	It is the same as size_t It is returned from the string size() member function It is returned from the string length() member function It is an unsigned integer type of some size You may create variables of that type
Compare C++ and Java string. Which of these are true?	"hello" is a string object in Java, but not in C++ String s; produces the null string in Java, while string s; produces the empty string in C++. String is capitalized in Java, lowercase in C++ Assuming str is a string, str + "b" is legal in both Java and C++
What header file do you include to call the isupper() function?	<cctype></cctype>
All of these are declared in the <string> header; which are member functions?</string>	size() front() find() at()
Match the letter of the variable in the figure with the correct value or expression below string s{"walk the plank"};	a:1 b:11 c:12 d:string::npos
auto a = s.find('a'); auto b = s.find('a', 3);	
auto b = s.find(a, 5); auto c = s.find("nk"); auto d = s.find("Walk");	
One-way, independent decisions use:	if
Either/or decisions should use:	if else
Multiple possible outputs, testing a single condition, use:	if else if else
Leveled decisions, such as processing income taxes are best handled with:	if if else else

To combine several test conditions to produce a single Boolean value, use:	a logical operator
In Line 2, what is the receiver?	s
string s{"happy"};	
auto pos = s.find('y');	
Decisions based on numbered blocks of code are best handled with:	switch
In Line 2, what is the result of this function call?	pos
string s{"happy"};	
auto pos = s.find('y');	
In Line 2, what is the request?	find
string s{"happy"};	
auto pos = s.find('y');	
In Line 2, what is the explicit argument?	'y'
string s{"happy"};	
auto pos = s.find('y');	
In Line 2, what is the implicit argument?	the address of s
string s{"happy"}; auto pos = s.find('y');	
In Line 2, what is the parameter?	None of these
	Notic of these
string s{"happy"}; auto pos = s.find('y');	
Assume c is a char variable. What type is the variable a?	char
string s{"guten tag"};	
auto len = s.size();	
auto a = s.front();	
s.at(len) = a;	
s[len] = c;	
Assume c is a char variable. What value s stored in the variable a?	'g'
string s{"guten tag"};	
auto len = s.size();	
auto a = s.front();	
s.at(len) = a; s[len] = c;	
What type is the variable len?	string::size_type
string s{"guten tag"};	
auto len = s.size(); auto a = s.front();	
s.at(len) = a;	
s[len] = c;	
Assume c is a char variable. What type is the expression s.last()?	None of these
string s{"guten tag"};	
auto len = s.size();	
auto a = s.front();	
s.at(len) = a; s[len] = c;	
spen c	
The relative order of two variables is tested using:	a relational operator
Assume c is a char variable. Which line throws an error because of range checking?	4
string s{"guten tag"}; // 1	
auto len = s.size(); // 2	
auto a = s.front(); // 3 s.at(len) = a; // 4	
s[len] = c; // 5	
Assume c is a char variable. Which line produces undefined behavior?	5
string s{"guten tag"}; // 1	
auto len = s.size(); // 2	
auto a = s.front(); // 3	
s.at(len) = a; // 4 s[len] = c; // 5	
S[Grig 6,77 6	

C+S+I	Study
string s{"guten tag"}; // 1 auto len = s.size(); // 2 auto a = s.front(); // 3 s.at(len) = a; // 4 s[len] = C; // 5	
	True
The string find() member function may be used to search for a substring	
The string find() member function takes either a string or character as an argument	True
The string find() member function throws an exception if the target cannot be found.	False
	· •
Calling s.at(1) returns a reference to the second character in the string object s	True
Calling s.at(1) returns a copy of the second character in the string object s	False
	True
s.at(0) = 'c'; changes the first character in the string object s to 'c'	
s.at(0) = "c"; changes the first character in the string object s to 'c'	False
The getline() function is part of the string class.	False
Data member is the term used in C++ for what is called a method in Java	False
The toupper() member function ignores case when it searches.	False
In C++ a char may be one, two or three bytes, when using UTF-8.	False
	True
Calling s.at(0) returns the same reference as s.front().	True
A C++ string that contains Unicode characters should be preceded by:	
To enter a Unicode character into a C++ string, use an escape sequence starting	\u
with:	
Which of these selects a character (char) from a string?	auto a = s[0];
This compiles, runs and prints 12. What is the correct parameter declaration for x?	int& x
This compiles, runs and prints 4, 3. What is the correct prototype?	void swap(int& a, int& b);
int x = 3, y = 4; swap(x, y);	
cout << x << ", " << y << endl;	
What value is stored in a after this runs?	3
string s{"ABCDEFD"};	
auto a = s.find('D');	1
What value is stored in a after this runs?	"defg"
string s{"abcdefg"}; auto a = s.substr(3);	
What value is stored in a after this runs?	Runtime error because start (4) must bet 03
string s{"ABC"}; auto a = s.substr(4, 5);	
What value is stored in a after this runs?	string::npos
string s{"ABCDEFD"};	
auto a = s.find('G');	
What value is stored in a after this runs?	"BCDE"
string s{"ABCDEFGHIJKLM"}; auto a = s.substr(1, 4);	
	by constant reference (const string& s) when not modified in the function.
String parameters should be passed to functions:	by reference (string& s) when modified in the function
Assume a is 5 and b is 3; what prints?	"the"
string s{"feed the fish"};	
cout << s.substr(a, b) << endl;	

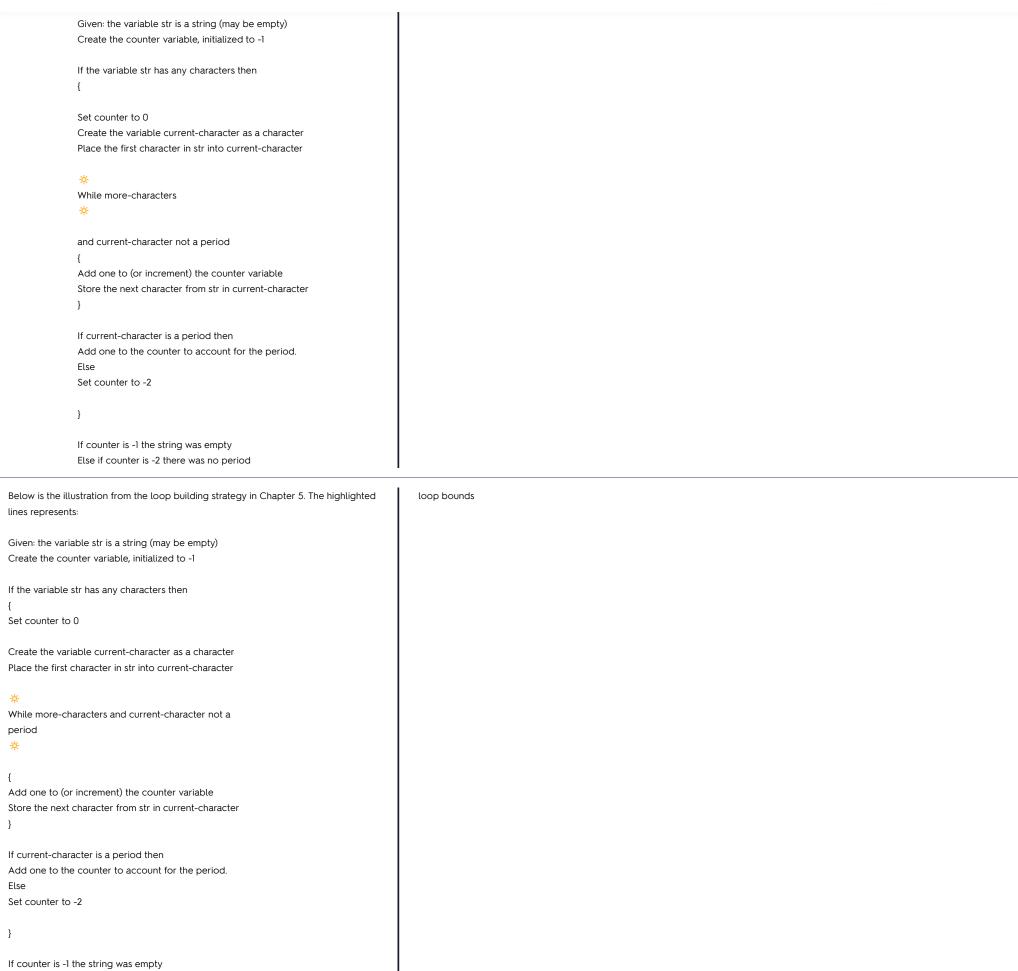

C.O.1	
string s{"feed the fish"}; cout << s.substr(a, b) << endl;	
Assume a is 13 and b is 10; what prints?	un .
string s{"feed the fish"}; cout << s.substr(a, b) << endl;	
Assume a is 14 and b is 10; what prints?	Runtime error
string s{"feed the fish"}; cout << s.substr(a, b) << endl;	
How many variables appear in the following code segment?	1
int n = 4;	
int& r1 = n; auto& r2 = r1;	
rl = 3;	
r2 = 5; cout << n << endl;	
What does this code segment print?	5
int n = 4;	
int& r1 = n;	
auto& r2 = r1; r1 = 3;	
r2 = 5;	
cout << n << endl;	
Which of these lines are illegal?	6
[1] int n1 = 4;	7
[2] double n2 = 3.145;	
[3] unsigned char n3 = 158;	
[4] int n4 = n2; [5] int& rl = n1;	
[6] int& r2 = n2;	
[7] double& r3 = n1;	
[8] const int& r4 = n2;	l .
Which of these lines are legal?	4
[1] int n1 = 4;	5 8
[2] double n2 = 3.145;	
[3] unsigned char n3 = 158;	
[4] int n4 = n2; [5] int& r1 = n1;	
[6] int& r2 = n2;	
[7] double& r3 = n1;	
[8] const int& r4 = n2;	
Which lines cause runtime errors (exceptions)?	None of these
[1] string s("shiver me timbers");	
[2] auto len = s.size(); [3] s.front() = 'S';	
[4] s.back() = "S";	
[5] s[len] = 'X';

★ Store the next character from str in current-character ★	
}	
If current-character is a period then Add one to the counter to account for the period. Else Set counter to -2	
}	
If counter is -1 the string was empty Else if counter is -2 there was no period	
Below is the illustration from the loop building strategy in Chapter 5. The highlighted lines represents:	loop postcondition
Given: the variable str is a string (may be empty) Create the counter variable, initialized to -1	
If the variable str has any characters then	
Set counter to 0 Create the variable current-character as a character Place the first character in str into current-character	
While more-characters and current-character not a period { Add one to (or increment) the counter variable Store the next character from str in current-character }	
*	
If current-character is a period then	
Add one to the counter to account for the period. Else Set counter to 21	
Set counter to -2]	
If counter is -1 the string was empty	
Else if counter is -2 there was no period	
In a guarded loop, the loop actions may never be executed	True
In a guarded loop, the loop actions are always executed at least once.	False
In an unguarded loop, the loop actions are always executed at least once.	True
In an unguarded loop, the loop actions may never be executed.	False
A guarded loop is also known as a test-at-the-top loop	True
A guarded loop is also known as a test-at-the-bottom loop.	False
An unguarded loop is also known as a test-at-the-bottom loop.	True
An unguarded loop is also known as a test-at-the-top loop.	False
Loops are used to implement iteration in C++.	True
Loops are used to implement selection in C++.	False

```
for (int i = 1; i <= 10; i++)
cout << i;
cout << endl;
This idiomatic pattern is used to count from one value to another. \\
for (int i = 1; i < 10; i++)
cout << i;
cout << endl;
                                                                                           False
                This loop uses asymmetric bounds.
                for (int i = 0; i < 10; i++)
                cout << i;
                cout << endl;
                                                                                           True
                This loop uses asymmetric bounds.
                for (int i = 1; i < 10; i++)
                cout << i;
                cout << endl;
                This loop uses asymmetric bounds.
                for (int i = 1; i <= 10; i++)
                cout << i;
                cout << endl;
                                                                                           False
        What prints?
        void fn(int, double, double&) { cout << "A" << endl; }</pre>
        void fn(int, int, double&) { cout << "B" << endl; }
        void fn(int, int, double) { cout << "C" << endl; }

Function overloading allows you to write several different functions that have the
same name.
Function overloading lets you call a single function in several different ways.
                                                                                                   False
                                                                                                   True
     Overloaded functions have the same name but different parameter types.
     Overloaded functions have the same name but different parameter names.
                                                                                                   False
               In a while loop, (condition) is followed by a semicolon.
                                                                                                   False
                A while loop is a hasty or unguarded loop.
                                                                                                   False
                               What prints here?
                               auto a = 1;
                               switch (a)
                               case 1: cout << "1"; break;
                               case 2: cout << "2"; break;
                               default: cout << "3";
                               cout << endl;
                               What prints here?
                                                                                                  2
                               auto a = 2;
                               switch (a)
                               case 1: cout << "1"; break;
                               case 2: cout << "2"; break;
                               default: cout << "3";
                               cout << endl;
```

C+S+I	Study
auto a = '1'; switch (a) { case 1: cout << "1"; break; case 2: cout << "2"; break;	
default: cout << "3"; } cout << endl;	
What prints here?	12
auto a = 1; switch (a) {	
<pre>case 1: cout << "1"; case 2: cout << "2"; } cout << endl;</pre>	
What prints here?	Does not compile
auto a = 1; switch (a) { case 1: cout << "1"; case 2: cout << "2"; case 3: } cout << endl;	
What prints here?	Undefined behavior
double a = 1; switch (a) { case 1: cout << "1"; case 2: cout << "2";	Orderined behavior
cout << endl;	
What prints here? auto a = 'A';	A But should be AB
switch (a) { case 64: cout << "?"; case 65: cout << "A"; case 66: cout << "B";	
cout << endl;	
The compiler determines which overloaded function to call by looking at the number, types and order of the arguments passed to the function.	True
Default arguments let you call a single function in several different ways.	True
Default arguments allow you to write several different functions that have the same name.	False
Default arguments may only be used with value parameters.	True
Default arguments may only be used with reference parameters.	False
Default arguments may be used with both value and reference parameters.	False
Default arguments appear only in the function prototype.	True
Default arguments appear only in the function implementation.	False
Fatal error messages should be printed to cerr.	True
Fatal error messages should be printed to cout. Calling break() terminates a program immediately and passes an error code back to the operating system.	False False
The compiler determines which overloaded function to call by looking at the type of value the function returns.	False
If str = "hello", then str.size() > -1.	False
Calling exit() terminates a program immediately and passes an error code back to the operating system.	True

CTSTI	Study
A do-while loop is also called a hasty loop.	True
In a do-while loop, (condition) is followed by a semicolon.	True
To allow f() to change the argument passed here, the parameter str should be declared as:	string&
void f(str); int main()	
{ string s = "hello"; f(s); }	
To allow f() to accept the argument passed here, the parameter str should be declared as:	const string&
void f(str); int main()	
{ f("hello"); }	
To allow f() to change the argument passed here, the parameter str should be declared as:	It is not possible for f() to change the argument passed here.
void f(str); int main()	
{ f("hello"); }	
	best match
A function where an argument is converted to match a parameter	ambiguity
When more than one match is found for the proffered arguments.	andgoty
A function where each argument is the same type as the corresponding parameter.	exact matches
A group of functions with the same name.	candidate set
A group of functions that have the same name and the correct number of parameters.	viable set
When no match is found for the proffered arguments	
	empty set
Examine the following variables and function calls Match each item with the correct statement below. int able = 3;	Returned value> baker Output argument (parameter)> Charlie
int baker = fl(able); cout << able << baker << endl; // 64	Input argument (parameter)> Hello
int charlie;	Input/output argument (parameter)> able
f2("hello", charlie); cout << charlie << endl; // Hello Carl	
Which of these are not ways that functions may be overloaded?	different function name different return type different parameter names
Different functions that have the same name, but take different arguments, are said to be:	overloaded
You can call a single function in several different ways by giving the function:	default arguments
Given the overloaded functions prototypes and the variable definition below, which of the function calls will fail to compile?	f(a);
<pre>int f(int&); int f(int); int f(int, int); int a = 7;</pre>	
Given the overloaded functions prototypes and the variable definition below, which of the function calls will fail to compile?	None of these fail to compile
<pre>int f(int&); int f(const int&); int f(int, int); int a = 7;</pre>	

```
int i = 1;
                 int n;
                 cin >> n;
                 do
                 {
                 j++;
                 cin >> n;
                 while (n % 2);
                 cout << i << endl;
                 Assume that the input is 5 5 4 3 5. What will print?
                                                                                                4
                 int i = 1;
                 int n;
                 cin >> n;
                 i++;
                 while (n % 2);
                 cout << i << endl;
                                   int i = 1;

Interface file	digits.h
Project file	makefile
Client file	digit tester.cpp
Implementation file	digits.cpp
The input stream member function for reading a character at a time is named:	get()
Assume you have a char variable named ch. How do you read one character from	cin.get(ch);
input?	
The expression cin.get(ch) does which of these?	reads the next character in input and stores it in ch
The expression charget(chy does which of these.	returns a reference to cin that can be tested
Assume you have a char variable named ch. How do you "unread" a character already read?	cin.putback(ch);
Assume you have a char variable named ch. How do you write one character to output?	cout.put(ch);
Complete the following code in the echo filter program.	cout.put(ch)
char ch;	
while (cin.get(ch));	
Complete the following code in the lower filter program.	tolower(ch)
char ch;	
while (cin.get(ch)) cout.put();	
Complete the following code in the upper filter program.	toupper(ch)
char ch;	
while (cin.get(ch)) cout.put();	
Complete the following code in the echo filter program.	cin.get(ch)
char ch;	
while () cout.put(ch);	
Assume the user types "brown cow" when this code runs. What type is ch2?	istream&
char chl;	
auto ch2 = cin.get(ch1);	
Assume the user types "brown cow" when this code runs. What prints?	Y
int n; if (cin >> n) cout << "X\n";	
else cout << "Y\n";	
Assume the user types "brown cow" when this code runs. What is stored in ch2?	cin
char chl; auto ch2 = cin.get(chl);	
Assume the user types "brown cow" when this code runs. What prints?	Does not compile
char c; cout.put(cin.get(c));	

char c; cout << cin.get(c) << endl;	
	True
When using cin >> ch; to read a character, leading whitespace is skipped.	
When using cin >> ch; to read a character, leading whitespace is not skipped.	False
Calling cout.put(65) prints the character 'A' on output	True
Calling cout.put(65) prints the number 65 on output	False
Calling cout.put(65) is illegal. Your code will not compile.	False
Calling cout.put(65.35) is illegal. Your code will not compile	False
When using the get() member function to read a character, leading whitespace is not skipped	True
When using the get() member function to read a character, leading whitespace is	
skipped.	False
A process filter does something to the characters it encounters	True
A process filter learns something about the stream by examining characters	
	False
The expression cin.get(ch) returns a reference to the input stream	True
The expression cin.get(ch) returns the next character from input	
	False
A state filter learns something about the stream by examining characters	True
A state filter does something to the characters it encounters	False
Counting the number of words in input by counting word transitions is an example of a state filter	True
Counting the number of words in input by counting word transitions is an example of a process filter.	False
You can test if an I/O operation succeeded by explicitly calling the stream's fail() member function	True
To test if an I/O operation succeeded you must explicitly call the stream's fail() member function	False
Calling cout.put(c) converts its argument, c, to a character.	True
Calling cout.put("A") is illegal. Your code will not compile.	True
When a stream is converted to a Boolean condition, its fail() member function is implicitly called	True
When using the get() member function, a stream will fail only if there are no	True
characters left in the input stream.	l
Programs that process streams of characters are called text	filters
	compress input by turning off echo when reading blank spaces
Which of these are not process filters?	print one sentence per line
	counting word transitions
Which of these superty that filters?	translating data from one form to another
Which of these are not state filters?	search for a particular value in a stream copy a file
Assume you have a char variable named ch. How do you look ahead before reading a character?	cin.peek();
Assume you have a char variable named ch. How do you look ahead before reading	cin.get(ch); cin.unget(ch);
a character?	cin.unget(ch); cin.putback(ch); cin.seek(ch);
2 Q U E S T I O N S	cin.peek(ch);
	> None of these

Which line runs the prt program and stores its output in a new file named x.data?		./prt > x.data
Which line runs the dmm program and adds its output to a file named x.data?	-	./dmm >> x.data
Which line runs the dd program and sends its errors to file named z.data?		./dd 2> z.data
Which line runs a.out getting its input from in.txt and appending its output to the file out.txt?		./a.out > in.txt >> outtxt
Which line runs a.out getting its input from in.txt and sending its output to the new file out.txt?		./a.out > out.txt < in.txt
Append output to a file named z		X
Discard both output and errors		rm x > /dev/null/2>&1
Write output to a new file named z		x
Read the input from the file named z		cat < z
Write errors to a new file named z		cat x 2>z
Send the output to the input of the program named z		date z
Which line runs the dom program and sends both output and errors to file named v.data?		./dom > v.data 2>&1
		get()
Has a single char& parameter		unget()
Returns the last character read to the input stream		peek()
Examines, but does not read the next character in an input stream		
Replaces the last character read with any character		putback()
Called implicitly when an input statement is used as a test condition.		fail()
A predicate function		isalpha()
Converts its value argument to a character and sends it to output.		
Which line runs a.out getting its input from in.txt and sending its output to the file out.txt, and its errors to the file err.txt?		./a.out < in.txt > outtxt 2> err.txt
Indefinite limit loop that reduces its input		while (n!=0) {n/=2;}
Indefinite limit loop that uses successive approximations		while(abs(g1-g2) >= EPSILON) {}
Counter-controlled symmetric loop for producing a sequence of data		for (int i = 12; i <= 19; i ++) {}
Indefinite data loop that uses raw input		while(cin.get(ch)) {}
Counter-controlled asymmetric loop for processing characters		for (size_t i = 0, len = s.size(); i < len; i++) {}
Iterator loop that may change its container		101 \Size_t 1 = 0, tell = 5.5ize(), 1 \ tell, 111) \{}
Iterator loop that cannot change its container		for(auto&e : col) {}
Counter-controlled loop for processing substrings		for(auto e: col) {}
Indefinite data loop that uses formatted input		for(size_t i=4, slen = 4; len = s.size(); i <len; i++)="" td="" {}<=""></len;>
indefinite data toop that uses formatted input		while(cin >> n)
A loop that reads data until some special value is found is called a:		sentinel loop
Which of these is not a technique for implementing a sentinel loop?		the counter-controlled pattern
What Java and other OO languages call a subclass, C++ calls a	I	derived class
Stream arguments to a function should:		be as general as possible (istream and ostream)
Stream arguments to a function should always be passed:	1	by reference
The file temp.txt contains "Orange Coast College". What prints?	<u> </u>	occ
ifstream in("temp.txt");		
char c; while (in.get(c))		
{ if (isupper(c))		
<pre>cout << toupper(c); }</pre>		

Which line opens the file in.txt for reading?	ifstream in("in.txt");
Which line opens the file input.txt for reading?	ifstream in("input.txt");
Create an input file stream object named in and open the text file "tuba.txt", using a single statement.	ifstream in("tuba.txt");
Create an output file stream object named out.	ofstream out;
Which line opens the file out.txt for writing?	ofstream out; outopen("outtxt");
Create an output file stream object named out and open the text file "expenses.dat", using a single statement.	ofstream out("expenses.dat");
Use the output stream object named out to create the text file on disk named "totals.txt".	out.open("totals.txt");
Establish an association between the input stream object named in, and the text file on disk named "pets.txt".	in.open("pets.txt");
Which line reads a single word from the istream named in into the string variable word?	None of these
word = in.next(); in.get(word); getline(in, word); in << word; None of these	
The file temp.txt contains "If I saw an Aardvark, I would scream!". What prints?	6
<pre>ifstream in("temp.txt"); char c; int i = 0; while (in.get(c)) { if (tolower(c) == 'a') i++; } cout << i << endl;</pre>	
The return value of the getline() function is an input stream object	True
The return value of the getline() function is a string object.	False
When writing a function with stream parameters, always use the most general type of stream that meets the specification	True
When writing a function with stream parameters, always use the most specific type of stream that meets the specification	False
The cout object is an instance of the ostream class.	True
The cout object is an instance of the ofstream class	False
A loop that reads data until the input stream signals that it is done is called a data loop	True
A loop that reads data until the input stream signals that it is done is called a sentinel loop	
	False
In the primed loop pattern, you read data before the loop and at the end of the loop.	True
loop.	True
In the primed loop pattern, you use Boolean flag to signal when the sentinel is found In the primed loop pattern, you use a break statement to exit the loop when the	True False
In the primed loop pattern, you use Boolean flag to signal when the sentinel is found In the primed loop pattern, you use a break statement to exit the loop when the sentinel is found The getline() function is a non-member function in the string library	True False True True
loop. In the primed loop pattern, you use Boolean flag to signal when the sentinel is found In the primed loop pattern, you use a break statement to exit the loop when the sentinel is found	True False

To use a disk file as a data stream source or sink, use the <fstream> header</fstream>	
To use a disk file as a data stream source or sink, use the <ifstream> header</ifstream>	False

In the C++ stream hierarchy, the base class of the ostream class is:		ios
In the C++ stream hierarchy, base class of the istream class is:		ios
In the C++ stream hierarchy, the base class of the stringstream class is:		iostream
In the C++ stream hierarchy, the base class of the fstream class is:		iostream
Read and write characters to memory using streams		sstream
Connect a disk file to an input or output stream		fstream
Use the predefined stream objects cin and cout		iostream
Determine the category of a character		cctype
Modify the way that memory is converted to characters on input or output		iomanip
Which fragment completes this code segment?		out.str()
string fmt(double n, int decimals)		
{ ostringstream out;		
out << fixed << setprecision(decimals); out << n;		
return;		
	<u> </u> -	
After writing data to an ostringstream object named os, you can retrieve the string it contains by using:	 -	os.str()
What does this code do?		Counts the number of characters in the file
ifstream in("temp.txt"); char x;		
int i{0};		
<pre>while (in.get(x)) i++; cout << i << endl;</pre>		
What does this code do?		Counts the number of lines in the file
ifstream in("temp.txt"); string x;		
int i{0};		
while (getline(in, x)) i++; cout << i << endl;		
What does this code do?		Counts the number of words in the file
ifstream in("temp.txt");		
string x; int i{0};		
while (in >> x) i++;		
cout << i << endl;	 	
Which of the following loop patterns are used here?		primed loop sentinel loop
size_t pos = 0; char ch;		
in.get(ch);		
while (ch != 'Q') {		
pos++; in.get(ch);		
)		
Which of the following loop patterns are used here?		inline test
int upper = 0;		data loop
char ch; while (in.get(ch))		
{		
if (ch >= 'A' && ch <= 'Z') upper++;		
}	<u> </u>	
Which of the following loop patterns are used here?		limit loop
int n;		
in >> n; while (abs(n))		
{ out << n % 4 << endl;		
n /= 4;		

auto len = str.size(); while (len) out << str.at(len);	
Which of the following loop patterns are used here? string s{"hello CS 150"}; for (auto e : s) { if (toupper(e)) out.put('x'); }	iterator or range loop
Which of the following loop patterns are used here? string s{"hello CS 150"}; for (auto e : s) { if (toupper(e)) break; }	iterator or range loop loop-and-a-half
<pre>Which of the following loop patterns are used here? string s{"Hello CS 150"}; while (s.size()) { if (s.at(0) == 'C') break; s = s.substr(1); } cout << s << endl;</pre>	counter-controlled loop loop-and-a-half sentinel loop
After opening the input stream in, which of these cannot be used to see if the file was successfully opened?	if (in.opened()) {/ opened ok /}
This loop: char c; while (in.get(c)) { cout << c << endl; }	illustrates raw character I/O
This loop: char c; while (c = in.get()) { cout << c << endl; }	illustrates line-based stream processing
This loop: string str; while (getline(in, str)) { cout << str << endl; }	illustrates line-based stream processing
This loop: string str; while (in >> str) { cout << str << endl; }	illustrates token-based stream processing
The file grades.txt contains lines of text that look like this: Smith 94 Jones 75 Each line of text contains the student's name (a single word) and an integer score. What is the legal way of reading one student's information, given the following code? string name;	in >> name >> score;
int score; ifstream in("grades.txt");	

```
ifstream in("expenses.txt");
    char c;
    while (in.get(c))
   if (isdigit(c)) {
    in.unget();
    double n;
   in >> n;
   cout << n << 'x';
   }
   }
   The file expenses.txt contains the line: Hotel, 3 nights. $ 1,750.25. What prints?
                                                                                                   3x1x750x25x
   ifstream in("expenses.txt");
    while (in.get(c))
   if (isdigit(c)) {
   in.unget();
   int n;
   in >> n;
   cout << n << 'x';
   }
   }
            Assume that the file scores.txt does not exist. What happens?
                                                                                                   Creates a new file, scores.txt and writes two lines of text.
            ofstream out("scores.txt");
            out << "Peter" << " " << 20 << endl;
            out << "John" << " " << 50 << endl;
              Which line represents the necessary bounds in this loop?
                                                                                                   2

                              // 3
                              ( e)
                              cout << e. () << endl;
                              // 4
The C++11 standard library provides the function stoi() to convert a string to an \,
                                                                                              string
integer. Which library is it found in?
                                                                                              #define
                                                                                              #ifdef
What preprocessor directive is not used when you wish to create blocks of code
                                                                                              #ifndef
that are only compiled under certain circumstances?
                                                                                              --> All of these may be used
Code that may cause an error should be placed in a _
                                                             _ block and code that
                                                                                              try, catch
handles the error should be inside a _____ block?
       The class ___ is the base of the classes designed to handle exceptions
                                                                                              exception
A(n) ___ is an occurrence of an undesirable situation that can be detected during
                                                                                              exception
program execution
What statement is used to signal other parts for your program that a particular error
                                                                                              throw
has occurred?
                                                                                              invalid_argument
   The class __ is designed to deal with illegal arguments used in a function call.
                                                                                              It is used to pass control to an error handler when an error situation is detected.
                    What is the purpose of the throw statement?
                The try block is followed by one or more ___ blocks.
                                                                                             catch
     Which of the following blocks is designed to catch any type of exception?
                                                                                              catch(...){ }
        The function ___ returns a string containing an appropriate message.
                                                                                              what
           A catch block can have, at most, ___ catch block parameter(s).
               What happens when this code fragment runs in C++ 11?
                                                                                              sqrt() returns a not-a-number error value
               cout << sqrt(-2) << endl;
   Variables tested with the #if preprocessor directive are created using #define
                                                                                             True
    Without try and catch, the throw statement terminates the running program
                                                                                             True
     A try block is a block of code where runtime or logical errors may occur
                                                                                             True
                 A catch(...) will catch any kind of thrown exception
                                                                                             True
        Functions with generic parameters are known as function templates.
                                                                                             True
A completion code is a special return value that means "the function failed to
execute correctly."
        Calling a function like to_string(3.5) is known as implicit instantiation
                                                                                             True
To use different versions of a function depending on the platform is called
                                                                                              True
conditional compilation.
Building your code with more than one copy of a function leads to a clash of
                                                                                              True
symbols.
                A template function may be defined in a header file.
                                                                                             True
The predefined constant _cpluplus indicates which version of the C++ standard is
                                                                                              True
being used
One of the main problems with the completion code strategy of error handling is
                                                                                              True
that callers can ignore the return value without encountering any warnings
      Calling a function like to string int>(3.5) is known as implicit instantiation.
                                                                                              False
```

The preprocessor operates on code after it has been compiled.		False
The directives #if defined(symbol) and #ifdef symbol mean, essentially, the same thing		True
The directives #if defined(symbol) and #ifndef symbol mean, essentially, the same thing.		False
A catch block may handle exception classes, as well as errors where int or string are thrown		Тгие
A catch block may only handle objects from classes derived from exception or logic_error		False
A catch block specifies the type of exception it can catch and immediately terminates the program		False
A catch block is a block of code where runtime or logical errors may occur		False
You can report a logical error encountered in your code by using the throw keyword		True
You can report a syntax error encountered in your code by using the throw keyword		False
Functions with generic parameters may use the keyword class or the keyword typename for their type parameters		Тгие
Functions with generic parameters may use the keyword class or the keyword struct for their type parameters		False
The #if preprocessor directive can compare integers		True
The #if preprocessor directive may compare double literals but not variables		False
The standard library version of sqrt(-2) returns the not-a-number error code		True
The standard library version of sqrt(-2) throws a runtime exception because there is no possible answer		False
You compiler or contains constants that can be used to identify the platform you are compiling on		True
A specialized error handling block of code, is called a catch block		Тгие
A specialized error handling block of code, is called a try block		False
The standard library version of stoi("UB-40") throws a runtime exception because there is no viable conversion		True
The standard library version of stoi("UB-40") returns the not-a-number error code.		False
The order of the catch blocks does not affect the program.		False
If no exception is thrown in a try block, all catch blocks associated with that try block are ignored.		True
When you throw an exception, control immediately jumps out of the current try block.		True
The preprocessor operates on code before it has been compiled.		False
The statement #if abs(-3) > 2 is legal.	I	False
A template function may be declared in a header file but must be defined in an implementation file.		False
The heading of a try block can contain ellipses in place of a parameter		False
When you throw an exception, control immediately returns from the current function	l	False
The line: ifstream in("x"); throws a runtime exception if a file x cannot be found		False
What happens when this code fragment runs?		stoi() returns 12
cout << stoi("12") << endl;

                                                                                                 Creates the vector [0]
                                                                                                 Points to the first element in \boldsymbol{v}
                                  v.begin()
                                  v.back();
                                                                                                 Returns a reference to the last element in \boldsymbol{v}
                             v.erase(v.begin());
                                                                                                 Removes the first element in \boldsymbol{v} and shifts the rest to the left
                               v.pop_back()
                                                                                                 Removes the last element in \boldsymbol{\nu}
                                                                                                 Returns a reference to the fourth element in \boldsymbol{v} with no range checking
                                    v[3];
                             vector<int>v(2,3);
                                                                                                 Creates the vector [3,3]
                                                                                                 Creates the vector [2, 3]
                             vector<int>v[2, 3];
                                                                                                 Adds a new element to the end of \nu
                              v.push_back(3);
                                   v.at(3);
                                                                                                Safely returns a reference to the fourth element in \boldsymbol{v}
```

Assume vector<int> v; Writing cout << v.front(); throws a runtime exception. (false)

Assume the vector v contains [1, 2, 3]. v.erase(v.begin() + 2); changes v to [1, 2].

The declaration: vector<string> v(5, "bob"); creates a vector containing five string objects, each containing "bob".

In the declaration: vector \leq int> v; the word int represents the object's base type.

The elements of a vector are allocated contiguously.

vector subscripts begin at 0 and go up to the vector size - 1

The clear() member function removes all the elements from a vector.

The statement v.insert(v.end() \star 1, 3) is undefined because end() \star 1 points past the last element in the vector.

The statement v.insert(v.end(), 3) appends the element 3 to the end of the vector v.

Contiguous allocation means that the elements are stored next to each other in memory.

The push_back member function adds elements to the end of a vector.

Assume the vector v contains [1, 2, 3]. v.erase(v.begin()); changes v to [2, 3].

The declaration: vector<int> v(10); creates a vector object containing ten elements initialized to 0.

Assume the vector v contains [1, 2, 3]. v.pop_back(); changes v to [1, 2].

The term for classes with a base-type specification are parameterized classes.

Assume that v contains [1, 2, 3]. The result of writing cout << v[4]; is undefined.

The C++ term for classes like vector are template classes.

A vector subscript represents the element's offset from the beginning of the vector.

The declaration: vector<string> $v{"bill", "bob", "sally"}$; creates a vector containing three string objects.

The declaration: vector<int> v(10, 5); creates a vector object containing ten integers.

Assuming that Star is a structure, the declaration: vector<Star> stars(3); creates three default initialized Star objects.

The declaration: vector<string> v(5); creates a vector containing five empty string objects.

Assume the vector v contains [1, 2, 3]. v.erase(0); is a syntax error.

The declaration: vector<int> v; creates a vector object with no elements.

A vector represents a linear homogeneous collection of data.

Assume vector<double> v; Writing cout << v.back(); is undefined.

Elements in a vector are accessed using a subscript.

The statement v.insert(v.begin(), 3) inserts the element 3 into the vector v, shifting the existing elements to the right.

C+S+I	Study
Vector subscripts begin at 1 and go up to the vector size.	
The statement v.insert(v.end(), 3) is undefined because end() points past the last element in the vector.	
Assume that v contains [1, 2, 3]. The result of writing cout << v.at(4); is undefined.	
The C++ term for classes like vector are generic classes.	
The statement v.insert(v.begin(), 3) inserts the element 3 into the vector v, overwriting the exiting element at index 0.	
The push_back member function adds elements to the end of a vector as long as there is room for the elements.	
The declaration: vector <int> v(10); creates a vector object containing uninitialized elements.</int>	
The declaration: vector <int> v(10, 5); creates a vector object containing five integers.</int>	
The declaration: vector <string> v(5); creates a vector containing five null pointers.</string>	
In the declaration: vector <int> v; the word vector represents the object's base type.</int>	
The declaration: vector <int> v; creates a vector variable but no vector object.</int>	
Assume that v contains [1, 2, 3]. The result of writing cout << v.at(4); is a compiler error.	
Vector subscripts begin at 1 and go up to the vector size.	
A vector consists of named members.	
The declaration: vector <int> v(10, 5); is illegal.</int>	
Assume vector <double> v; Writing cout << v.back(); throws a runtime exception.</double>	
Assume that v contains [1, 2, 3]. The result of writing cout $<<$ v[4]; is a compiler error.	
The declaration: vector <int> v = new vector<>(); creates a vector object with no elements.</int>	
The pop_back member function adds elements to the end of a vector.	
Examine the following code (which is legal). What is the correct prototype for an aggregate output operator?	ostream& operator<<(ostream& out, const Time& m);
struct Time { int hours{0}, minutes{0}, seconds{0}; };	
Examine the following code (which is legal). What is the correct prototype for an aggregate output operator?	ostream& operator<<(ostream& out, const Money& m);
struct Money { int dollars{0}, cents{0}; } m1, m2;	
Examine the following code (which is legal). Which statement is illegal?	cout << m1 << endl;
struct Money { int dollars{0}, cents{0}; } m1, m2;	
Examine the following code (which is legal). Which statement is legal?	m1 = m2;
struct Money { int dollars{0}, cents{0}; } m1, m2;	
Examine the following code (which is legal). Which statement is correct?	Rectangle r;
struct Rectangle { int length, width; };	
The following is legal. Which is the correct way to access a data member in the Rectangle variable named r?	r.length
struct Rectangle { int length, width; };	
The structure and variable definitions are fine. Which statements are legal?	if (big.length == small.width)
struct Rectangle { int length, width; } big, small;	
The following is legal. Which changes the length data member inside the variable big?	big.length = 10;
struct Rectangle { int length, width; } big, little;	
Examine the following code (which is legal). What changes are necessary to allow the statement if (m1 == m2) to compile?	The name of equals() must be changed to operator==
struct Money { int dollars{0}, cents{0}; } m1, m2;	
bool equals(const Money& lhs, const Money& rhs)	
{ return lhs.cents == rhs.cents && lhs.dollars == rhs.dollars;	

struct Money { int dollars{0}, cents{0}; } ml, m2;	
bool equals(const Money& lhs, const Money& rhs)	
return lhs.cents == rhs.cents &&	
lhs.dollars == rhs.dollars; }	
Examine the following definition. What is the syntax error?	missing a semicolon after the structure definition
struct Employee

std::string lastName; double salary;	
int age;	
};	
Employee bob{}:	

struct Employee { long empID; std::string lastName; double salary; int age; }; Employee bob{777, "Zimmerman"};	
Given the following structure and variable definitions, which data members are default initialized?	None of these
struct Employee { long empID; std::string lastName; double salary; int age; }; Employee bob{777, "Zimmerman", 5000000.0, 76};	
Given the following structure and variable definitions which statements are legal? struct Money { int dollars{0}; int cents{1}; }; Money payment;	cout << payment.dollars; payment.cents = 5;
Given the following structure and variable definitions which statements are illegal? struct Money { int dollars{0}; int cents{1}; }; Money payment;	<pre>payment{1} = 5; cout << Money,dollars; Money{1} = Money{0};</pre>
The structure and variable definitions are fine. Which statements are legal? struct R $\{$ int a, b; $\}$ a, b; struct Q $\{$ int a, b; $\}$ c, d;	c = d;
YOUDONOTNEEDTOREVIEWFORTRUE/FALSE	YOUDONOTNEEDTOREVIEWFORTRUE/FALSE

Structures are heterogeneous data types.

The built-in primitive data types such as int, char and double are scalar data types.

User-defined scalar types are created with the enum class keywords in C++.

User-defined types that contain a single value are called scalar types.

The standard library types such as string and vector are structured data types.

You may create a structure variable as part of a structure definition.

The following is an anonymous structure. struct {int hours, seconds; } MIDNIGHT{0, 0};

Structure variables should be passed to functions by reference.

When passing a structure variable to a function, use non-const reference if the intent is to modify the actual argument.

The following code is legal. struct {int hours, seconds; } MIDNIGHT{0, 0};

User-defined types that combine multiple values into a single type are called structured types.

A structure member may be a variable of a different structure type.

In C++, objects have value semantics; object variables contain the data members.

Structures data members may each have a different type.

C++ has two ways to represent records, the class and the struct.

This is the correct syntax for a C++ scoped enumeration. enum class WEEKEND {SATURDAY, SUNDAY};

It is illegal to include the same struct definition multiple times, even if the definitions are exactly the same.

When passing a structure variable to a function, use const reference if the function should not modify the actual argument.

In Computer Science, a collection of variables that have distinct names and types is called a record.

This is the correct syntax for a C++ plain enumeration. enum WEEKEND $\{SATURDAY, SUNDAY\};$

User-defined types that combine multiple values into a single type are called scalar types It is legal to include the same struct definition multiple times, as long as the definitions are exactly the same. In C++, objects have reference semantics; object variables refer to, but do not contain the data members. A structure definition creates a new variable. In C++, a collection of variables that have distinct names and types is called a record. In C++, a collection of variables that have distinct names and types is called a structure. User-defined types that contain a single value are called structured types. This is the correct syntax for a C++ scoped enumeration. enum WEEKEND {SATURDAY, SUNDAY}; Structure variables should be passed to functions by value. User-defined scalar types are created with the struct or class keywords in C^{++} . Structures are homogenous data types. User-defined types that combine multiple values into a single type are called scalar types. Structures data members must all be of the same type. When passing a structure variable to a function, use non-const reference if the function should not modify the actual argument. types. When passing a structure variable to a function, use const reference if the intent is to modify the actual argument. The standard library types such as string and vector are scalar data types. The following code is illegal. struct {int hours, seconds; } MIDNIGHT{0, 0}; [1301] Which line below points ppi to pi? ppi = π int main() double pi = 3.14159; double *ppi; // code goes here // code goes here [1302] Assume that ppi correctly points to pi.                                                                                                                                                                                                                                                                                   *(p) = *(p + 1) = *(p + 2) = 0;
statement sets the red, green and blue components to 0?
Let \ensuremath{\mathsf{p}} point the beginning of the image
Set end to point just past the end
While p != end
If *(p + 3) is 0 (transparent)
Clear all of the fields
Increment p by 4
[1351] Here is a fragment of pseudocode for the negative() function in H12. What
                                                                                                                                                                                                                                                                                  p++;
statement represents the underlined portion of code?
Let p point to beginning of the image
Let end be pixel one past the end of the image
While p != end
Invert the red component
Move p to next component
Used to access the data inside a variable
                                                                                                                                                                                                                                                                                  variable name
Determines the amount of memory required and the operations permitted on a
                                                                                                                                                                                                                                                                                  variable type
variable
                                                                                                                                                                                                                                                                                  variable value
The meaning assigned to a set of bits stored at a memory location % \left( x\right) =\left( x\right) +\left( x\right) +
                                                                                                                                                                                                                                                                                  pointer
An object whose value is an address in memory
                                                                                                                                                                                                                                                                                  p = &a;
Expression using the address operator
                                                                                                                                                                                                                                                                                  int x = 3;
Expression using the reference declarator
                                                                                                                                                                                                                                                                                  y = *a;
Expression using the dereferencing operator
                                                                                                                                                                                                                                                                                  double * v;
Expression using the pointer declarator
                                                                                                                                                                                                                                                                                  sizeof(Star)
Expression returning the number of allocated bytes used by an object
                                                                                                                                                                                                                                                                                  nullptr
Address value 0
                                                         [1401] Which of these lines correctly prints 3?
                                                                                                                                                                                                                                                                                 cout << (*p).a << endl;

In C++ using == to compare one array to another is permitted (if meaningless).

You must use an integral constant or literal to specify the size of a built-in C++ array.

The reinterpret_cast instruction changes way that a pointer's indirect value is interpreted.

If p is a pointer to a structure, and the structure contains a data member x, you can access the data member by using the notation: (*p).x

C++ arrays have no support for bound-checking.

In C++ assigning one array to another is illegal

The allocated size of a built-in C++ array cannot be changed during runtime.

The size of the array is not stored along with its elements.

If img is a pointer to the first byte in an image loaded into memory, Pixel is a structure as defined in your textbook, you can create a Pixel pointer pointing to the image by writing:

Pixel **p = reinterpret_cast<Pixel** >(img);

The subscripts of a C++ array range from 0 to the array size - 1.

C++ arrays have no built-in functions for inserting and deleting.

A forward reference can be used when you want to use a pointer to a structure as a data member without first defining the entire structure.

The elements of a C++ array created in a function are allocated on the stack.

The elements of a C++ array created outside of a function are allocated in the static-storage area.

The elements of a C++ string array with no explicit initialization, created in a function will be set to the empty string.

Explicitly initializing an array like this: int $a[3] = \{1, 2, 3\}$; requires the size to be the same or larger than the number of elements supplied.

In C++ printing an array name prints the address of the first element in the array.

In C++ there is no separate array variable. The array name is a symbolic representation of the address of the first element in the array.

In C++ initializing an array with the contents of another is illegal.

C++ arrays produce undefined results if you access an element outside the array.

Explicitly initializing an array like this: int a $[=\{1, 2, 3\}$; works in all versions of C++.

C+S+I Study You may use any kind of integral variable to specify the size of a built-in C++ array. The elements of a C++ string array with no explicit initialization, created in a function will be set to null. Explicitly initializing an array like this: int a[3] = $\{1, 2, 3\}$; requires the size to be the same or smaller than the number of elements supplied. In C++ using == to compare one array to another is illegal. The allocated size of a built-in C++ array may be changed during runtime If img is a pointer to the first byte in an image loaded into memory, Pixel is a structure as defined in your textbook, you can create a Pixel pointer pointing to the image by writing: Pixel **p = static_cast<Pixel** >(img); The reinterpret_cast instruction produces a temporary value by converting its argument. In C++ initializing an array with the contents of another is permitted. C++ arrays use bound-checking when you access their elements with the at() The elements of a C^{++} array created in a function are allocated on the heap. In C++ assigning one array to another is permitted. C++ arrays throw an out_of_bounds exception if you access an element outside the array. In C++ an array variable and the array elements are separate. The array variable contains the address of the first element in the array. In C++ printing an array name prints the value of the first element in the array. The elements of a C++ int array with no explicit initialization, created in a function will be set to zero. C++ arrays can be allocated with a size of 0. The static_cast instruction changes way that a pointer's indirect value is interpreted. The size of the array is stored along with its elements. The allocated size of a built-in C++ array may be changed during runtime A forward reference can be used when you want to use a structure as a data member without first defining the entire structure. The elements of a C++ array created outside of a function are allocated on the stack. If p is a pointer to a structure, and the structure contains a data member \boldsymbol{x} , you can access the data member by using the notation: p-xC++ arrays offer built-in member functions for inserting and deleting. Explicitly initializing an array like this: int a $[= \{1, 2, 3\};$ only works in C++ 11. [1501] Below is a cumulative algorithm using an array and a range-based loop. What sum->20 is printed? (Assume this is inside main() with all includes, etc.) int a[] = {2, 4, 6, 8}; int sum = 0; for (auto e : a) sum += e; cout << "sum->" << sum << endl; Compiles but crashes with an endless loop. Does not compile. Cannot use range-loop on arrays. sum->20 sum->0 Compiles and runs, but results are undefined. [1502] Below is a cumulative algorithm using an array and a range-based loop. ```

Fence-post algorithm

An array passed to a function decays to a pointer.

An array passed to a function f(int * const a, ...) may have its elements changed.

The elements of an array may be allocated on the stack.

If p points to the first element in [1, 3, 5] then cout << ++*p prints 2.

The library function begin(a) returns a pointer to the first element in the array a.

The elements of an array may be allocated in the static storage area.

Arrays generally have higher performance than a vector.

The function mystery(const int, const int) likely employs an iterator loop.

The expression begin(a) + 1 returns a pointer to the second element in the array a.

Array subscripts are not range checked

An array passed to a function is passed by address.

If size_t len = 0; then len - 1 is the largest possible unsigned number.

If p points to the first element in [1, 3, 5] then cout << *++p prints 3.

The algorithm that finds the address of the smallest element in an array is called an extreme values algorithm.

The expression p++ means the same as (p++).

Before passing an array to a function, sizeof(a)/sizeof(a[0]) will tell the number of elements in the array.

For systems programming (such as operating systems), arrays are used more often

The library function $\operatorname{end}(a)$ returns a pointer to position right past the last element in the array a.

For embedded systems, arrays are preferred over vector.

The parameter declarations int *p and int p[] mean the same thing.

The algorithm that prints elements separated by commas is called the fencepost algorithm.

The elements of a vector are allocated on the heap.

A vector variable may be allocated on the stack.

Before passing an array to a function, sizeof(a) will tell you the array's allocated size, but not the number of elements.

After passing an array to a function, sizeof(a)/sizeof(a[0]) will tell the number of elements in the array.	
If p points to the first element in [1, 3, 5] then cout $<<$ *++p prints 1.	
If p points to the first element in [1, 3, 5] then cout $<<++*p$ prints 1.	
The library function begin(a) returns a pointer to the element right before the first in the array a.	
For embedded systems, vector is preferred over arrays.	
For systems programming (such as operating systems), vectors are used more often than arrays.	
For an equivalent number of elements, a vector will use less memory than an array.	
The expression p++ means the same as (p)++.	
An array passed to a function f(const int *a,) may have its elements changed.	
The elements of a vector may be allocated on the stack.	
For an equivalent number of elements, a vector will use more memory than an array.	
The algorithm that prints elements separated by commas is called a cumulative algorithm.	
The algorithm that finds the position of the largest element in an array is called a cumulative algorithm.	
The algorithm that finds the position of the largest element in an array is called a cumulative algorithm.	
After passing an array to a function, sizeof(a) will tell you the array's allocated size, but not the number of elements.	
If p points to the first element in [1, 3, 5] then cout << *p++ prints 3.	
The library function end(a) returns a pointer to the last element in the array a.	
A vector generally has higher performance than an array.	
If size_t len = 0; then len - 1 is the smallest possible unsigned number.	
The expression begin(a) + 1 returns a pointer to the first element in the array a.	
The function mystery(const int, const int) likely employs a counter-controlled loop.	
An array passed to a function is passed by reference.	
[1601] Below is a partially-filled array. If you are adding elements to this array in a loop, what is the correct loop bounds condition?	while (size < MAX)

bool insert(double a[], size_t size, size_t MAX, double e, size_t pos);	
bool insert(double a[], size_t& size, size_t MAX, double e, size_t pos);	
[1607] Below is a declaration for a partially-filled array. What is the correct prototype for a function delete() that deletes the element at position pos in the array, shifts the remaining elements left, and returns true if successful?	bool delete(double a[], size_t& size, size_t pos);
const size_t MAX = 100; double nums[MAX]; size_t size = 0;	
bool delete(double a[], size_t size, size_t pos);	
bool delete(double a[], size_t& size, size_t pos);	
bool delete(double a[], size_t MAX, size_t& pos);	
bool delete(const double a[], size_t& size, size_t pos);	
[1608] Below is a mystery() function with no types for its parameter. What does the function do?	Appends input to the end of a partially-filled array.
void mystery(a, b&, c, d, e)	
b = 0; while (in >> n && b < c) a[b++] = n; }	
Inserts input into a partially-filled array Deletes elements from a partially-filled array Appends input to the end of a partially-filled array.	

```
void mystery(a, b&, c, d, e)
for (i = d; i < b; i++)
a[i] = a[i + 1];
Inserts input into a partially-filled array
Deletes elements from a partially-filled array
Appends input to the end of a partially-filled array.
[1610] Below is a mystery() function with no types for its parameter. What does the
                                                                                                  Inserts input into a partially-filled array
function do?
void mystery(a, b&, c, d, e)
for (i = b; i > d; i--)
a[i] = a[i - 1];
a[d] = e;
b++;
Inserts input into a partially-filled array
Deletes elements from a partially-filled array
Appends input to the end of a partially-filled array.
                                                                                                  size should be incremented
[1611] Below is a template function, push(), that adds elements to the end of a
partially-filled array, returning true if successful. The function has an error; what is
the error?
template <typename T>
bool push(T* a, size_t& size, size_t MAX, T e)
if (size < MAX) {
a[size] = e;
return true;
return false;
a should be a const T*
size should be incremented
size should be passed by value
Condition should be size <= MAX
[1612] Below is pop(), a template function that works with a partially-filled array. The
                                                                                                  The wrong value is assigned to e
function copies the last element in the array into the output parameter \ensuremath{\text{e}} and returns
true if successful; it returns false otherwise. What is the error?
template <typename T>
bool pop(T* a, size_t& size, T& e)
if (size) {
e = a[size];
return true;
return false;
a should be a const T*
Condition should be !size
size should be incremented
The wrong value is assigned to e
[1613] Below is index(), a template function that works with a partially-filled array. The
                                                                                                  size should not be passed by reference
function searches the array a for the value e and returns its position. It returns
NOT_FOUND if the value does not it exist in the array. The function contains an error;
what is the error?
const size_t NOT_FOUND = static_cast<size_t>(-1);
template <typename T>
size_t index(const T* a, size_t& size, T e)
for (size_t i = 0; i < size; i++)
if (a[i] == e) return i;
return NOT_FOUND;
a should not be a const T*
e should be passed by reference
The condition should go to i <= size
size should not be passed by reference
```

```
removed. The function contains an error; what is the error?
template <typename T>
int remove(T* a, size_t& size, T e)
int removed = 0;
size_t i = 0;
while (i < size)
if (a[i] == e)
removed++;
size--;
for (size_t j = i; i < size; i++)
a[i] = a[i + 1];
return removed;
a should be a const T*
size should not be passed by reference
The condition should go to while (i \leftarrow size)
Not all copies of e are necessarily removed
[1615] Below is insert(), a template function that works with a partially-filled array. The
                                                                                                     If there is room to insert, the function returns false instead of true % \left\{ 1,2,...,n\right\}
function inserts the argument e into the array, in sorted order. The function returns
true if it succeeds, false otherwise. The function contains an error; what is the error?
template <typename T>
bool insert(T* a, size_t& size, size_t MAX, T e)
if (size < MAX) return false;
size_t i = 0;
while (i < size)
if (a[i] > e) break;
j++;
for (j = size; j > i; j--)
a[j] = a[j - 1];
a[i] = e;
size++;
return true;
The value is inserted into the wrong position
The second loop should start at i and go up to size
When a value is inserted, it erases one of the existing values
If there is room to insert, the function returns false instead of true
[1616] Below is insert(), a template function that works with a partially-filled array. The
                                                                                                     If the array is full, the function overwrites memory outside the array.
function inserts the argument e into the array, in sorted order. The function returns
true if it succeeds, false otherwise. The function contains an error; what is the error?
template <typename T>
bool insert(T* a, size_t& size, size_t MAX, T e)
if (size < MAX) return false;
size_t i = 0;
while (i < size)
if (a[i] > e) break;
for (j = size; j > i; j--)
a[j] = a[j - 1];
a[i] = e;
size++;
return true;
The value is inserted into the wrong position
The second loop should start at i and go up to size
When a value is inserted, it erases one of the existing values
If the array is full, the function overwrites memory outside the array
```

```
true if it succeeds, false otherwise. The function contains an error; what is the error?
template <typename T>
bool insert(T* a, size_t& size, size_t MAX, T e)
if (size >= MAX) return false;
size_t i = 0;
while (i < size)
if (a[i] > e) break;
j++;
for (j = size; j > i; j--)
a[j] = a[j - 1];
a[i] = e;
return true;
The value is inserted into the wrong position
The second loop should start at i and go up to size
Every time the function is called, an array element is "lost"
The function writes over memory outside the array when it should not
          [1618] Which loop is used when inserting an element into an array?
                                                                                                      for (j = size; j > pos; j--) a[j] = a[j - 1];

```
void stringCopy(char *p, const char *q)
      while ((*p = *q) != '\0') {
      p++;
      q++;
     }
      No, because there is no *p = '\0'; after the loop
      No, because the comparison should be against 0, not against '\0'
      No, because the condition accidentally used = instead of ==
      Yes, the terminator is copied as the condition fails
      No, because there is no actual copy of characters into p at all
          [1724] Which while condition makes this function correct?
                                                                                            *s1 == *s2 && *s1 && *s2

C+S+I Study The characters for the C-string char * s1 = "hello"; are stored in user memory and may be modified. strcmp(sl, s2) returns true if s1 and s2 contain the same characters. The strlen() function returns the allocated size of a C-string allocated as an array. The C-string type is part of the standard library, not built into the C++ language. C-string assignment uses the = operator. The length of a C-string is stored explicitly in its length data member The allocated size for the C-string char s1[1024] = "hello"; is 6 characters, while the effective size is 5 characters. C-string assignment uses the strcat() function. The strcat() function cannot overflow the storage allocated for the destination $% \left(1\right) =\left(1\right) \left(1\right) \left$ buffer. The strncpy() function always appends a trailing NUL when the copy is finished. strcmp(s1, s2) returns a negative number if s1 is lexicographically "greater than" s2. The sizeof operator returns the effective size of a C-string allocated as an array. The strncpy() function is straightforward and easy to use. strcmp(s1, s2) returns a positive number if s1 is lexicographically "less than" s2. You can compare two C-strings, s1 and s2, by using the == operator. C-strings use the + operator for concatenation. C-strings are char pointers to the first character in a sequence of characters,

Mac OSX or Linux, you will normally use the C++ library string type, rather than the older C-string type.

The C-string literal "cat" contains 3 characters.

terminated with a '0' character.

The strcpy() function expands the destination string to make sure it is large enough to hold the source string.

When writing programs that interact with your operating system, either Windows,

You can compare two C-strings, si and sz, by using the strcmp() function.	
C-strings are character arrays that rely on a special embedded sentinel value, the character with the ASCII code 0.	
The allocated size for the C-string char s1[] = "hello"; is 6 characters, while the effective size is 5 characters.	
The sizeof operator returns the allocated size of a C-string allocated as an array.	
The effective size of the C-string char * s1 = "hello"; is 5 characters, but 6 characters are used for storage.	
strcmp(s1, s2) returns a positive number if s1 is lexicographically "greater than" s2.	
C-strings use the strcat() function for concatenation.	
The strlen() function returns the effective size of a C-string.	
C-strings are often needed to interoperate with legacy C libraries.	
When writing programs that interact with your operating system facilities, either Windows, Mac OSX or Linux, you will normally use C-strings instead of the C++ library string type.	
The characters for the C-string char sl[] = "hello"; are stored in user memory and may be modified.	
C-strings are char pointers to the first character in a sequence of characters, terminated with a '\0' character.	
C-string functions may be more efficient than C++ string member functions.	
strcmp(s1, s2) returns a negative number if s1 is lexicographically "less than" s2.	
Given the C-string char * s3 = "hello"; strlen(s3) returns 5.	
C-string assignment uses the strcpy() function.	
strcmp(s1, s2) returns 0 if s1 and s2 contain the same characters.	
The C-string type is built into the C++ language, not defined in the standard library.	
The strcpy() function always appends a trailing NUL when the copy is finished.	
The strncpy() function can be used to make sure that you don't copy more characters than necessary.	
Programs written for embedded devices often use C-strings rather than the C++ library string type.	
The length of a C-string is never stored explicitly	
The C-string literal "cat" contains 4 characters.	
The strncat() function allows you to limit the maximum number of characters that are concatenated.	
The character with the ASCII code 0 is called the NUL character	
[1801] Which of these is a 2D array?	int c[2][2];

You can pass the first row of the 2D array int a[3][3] to the function f(int *a, size_t n) by calling f(a[0], 3).	True
You can pass the 2D array int a[3][3] to the function f(int *a, size_t r, size_t c) by calling f(&a[0][0], 3, 3).	True
Physically, a 2D array is stored as a single linear, contiguous array with the elements for each column following the elements for the previous column in memory.	False
Command line arguments that start with a hyphen are usually called switches.	True
You can use a range-based loop on a 2D array.	True
You can pass the 2D array int a[3][3] to the function f(int a[3][], size_t n) by calling f(a, 3).	False
Physically, a 2D array is stored as a single linear, contiguous array with the elements for each row following the elements for the previous row in memory.	True
A 2D array address expression is the equivalent of: (address + (row height + col))	False
You cannot use a range-based loop on a 2D array.	False
You can pass the first column of the 2D array int a[3][3] to the function f(int *a, size_t n) by calling f(a[0], 3).	False
You can pass the 2D array int a[3][3] to the function f(int a[][3], size_t n) by calling f(a, 3).	True
In a 2D array the first subscript represents the rows and the second the columns.	True

A 2D array address expression is the equivalent of: (address + (row width + col))		True
When initializing a 2D, each row must have its own set of braces.		False
When passing a 2D array to a function, the array parameter must explicitly list the size for all dimensions except for the last, like: void f(int a[3][], size_t n);		False
A 2D array is a 1D array whose elements are also 1D arrays.		True
The rules for partial initialization of a 2D array can be changed by adding braces around interior array elements.		True
You can pass the 2D array int a[3][3] to the function f(int a[][], size_t r, size_t c) by calling f(a, 3, 3).		False
Your operating system's command processor is known as the shell.	l	True
When initializing a 2D, each column must have its own set of braces.		False
You can pass the 2D array int a[3][3] to the function f(int *a, size_t r, size_t c) by calling f(a, 3, 3).		False
Conceptually, a 2D array is rectangular grid of columns and rows.		True
Physically, a 2D array is stored as a rectangular grid of columns and rows.		False
When passing a 2D array to a function, the array parameter must explicitly list the size for all dimensions except for the first, like: void f(int a[[3], size_t n);		True
In a 2D array the first subscript represents the columns and the second the rows.		False
On the command line, argc is the count of arguments including the program itself.	1	True

A unique_ptr uses a reference count to manage how many pointers point to an
                                                                                              False
object.
            To allocate memory on the heap, C^{++} uses the new operator.
                                                                                              True
Memory for global variables is allocated when the program is loaded from disk. This
                                                                                              False
is known as dynamic allocation.
     The statement new int{3}; allocates an array of three integers on the heap.
                                                                                              False
     The statement new int\{3\}; allocates a single initialized integer on the heap.
                                                                                              True
Memory for local variables is allocated on the stack when their definitions are
                                                                                              False
encountered during runtime. This is known as dynamic allocation.
Requesting a block of memory from the operating system as the program runs is
                                                                                              False
known as static allocation.
Memory for global variables is allocated when the program is loaded from disk. This
                                                                                              True
is known as static allocation.
             Smart pointers may point to objects allocated on the stack.
                                                                                              False
Assuming p is a pointer to a single variable allocated on the heap, the statement
                                                                                              False
delete[] p; returns the allocated memory back to the operating system for reuse.
A pointer that goes out of scope before deleting the memory it points to is called a
                                                                                              False
double delete.
A pointer-like object that can be used to automatically manage memory allocated
                                                                                              True
Memory for global variables is allocated when the program is loaded from disk. This
is known as automatic allocation.
The release() function returns the raw pointer that a unique_ptr contains before
                                                                                              True
seting the pointer to nullptr.
                                                                                              False
Assuming p is a pointer to a single variable allocated on the heap, the statement
delete p; sets the pointer to nullptr so that the memory can be reused for another
allocation.
Memory for local variables is allocated on the stack when their definitions are
                                                                                              False
encountered during runtime. This is known as static allocation.
     The statement new int\{3\}; allocates an array of three integers on the heap
                                                                                              False
Using a pointer to access the memory it points to after the pointer has been deleted
                                                                                              False
is called a double delete.
```

A pointer that goes out of scope before deleting the memory it points to is called a memory leak.	True
If the new operator cannot allocate memory, C++ throws an exception.	True
The statement new int{}; is a syntax error.	False
Using a pointer to access the memory it points to after the pointer has been deleted is called a memory leak.	False
The reset() function returns the raw pointer that a unique_ptr contains, before setting that pointer to nullptr.	False
To transfer a unique_ptr to a vector, use push_back along with the move() function.	True
The statement new int[3]{1, 2, 3}; allocates an array of three initialized integers on the heap.	True
Requesting a block of memory from the operating system as the program runs is known as dynamic allocation.	True
Assuming p is a pointer to the first variable in an array allocated on the heap, the statement delete[] p; returns the allocated memory back to the operating system for reuse.	True
The statement new int[3] = {1, 2, 3}; is a syntax error.	True
The statement new int[3](); allocates an array of three default-initialized integers on the heap.	True
The statement new int[3]; allocates an array of three uninitialized integers on the heap.	True
The statement new int{}; allocates a default-initialized integer on the heap.	True
Freeing unused memory that was allocated elsewhere in your program is done in C++ using a garbage collector.	False
The statement new int[3](); is a syntax error.	False
Using a pointer to access the memory it points to after the pointer has been deleted is called a dangling pointer.	True
A unique_ptr can refer to a dynamic array.	True
A unique_ptr may transfer its ownership to another unique_ptr.	True
Assuming p is a pointer to a single variable allocated on the stack, the statement delete p; returns the allocated memory back to the operating system for reuse.	False
Freeing unused memory that was allocated elsewhere in your program is done in C++ using manual memory management.	True
The release() function deletes the raw pointer that a unique_ptr contains, and then sets that pointer to a new value.	False
Assuming p is a pointer to the first variable in an array allocated on the heap, the statement delete p; returns the allocated memory back to the operating system for reuse.	False
A shared_ptr uses a reference count to manage how many pointers point to an object.	True
A pointer that goes out of scope before deleting the memory it points to is called a dangling pointer.	False
To allocate memory on the stack, C++ uses the new operator.	False
The statement new int; allocates an uninitialized integer on the heap.	True
Smart pointers automatically delete the memory they point to at the appropriate time.	True
Assuming p is a pointer to a single variable allocated on the heap, the statement delete p; returns the allocated memory back to the operating system for reuse.	True
If the new operator cannot allocate memory, C++ returns nullptr.	False
The statement new int; allocates an uninitialized integer on the stack.	False
The statement new int[3] = {1, 2, 3}; allocates an array of three initialized integers on the heap.	False

A pointer-like object that can be used to automatically manage memory allocated on the heap is called a raw pointer.	False
Requesting a block of memory from the operating system as the program runs is known as automatic allocation.	False

With classes, the public interface includes the member functions that allow clients to access object data in a safe way as well as the data members themselves.		False	
In C++ you use the keyword public or private to create a section that indicates the access privileges of subsequent data members or member functions.		True	
Member functions that change the state of an object are called constructors.		False	
The member function int hours() const; provides read-write access to the hours property (however it is stored).		False	
A class is an interface paired with an implementation.	<u> </u>	True	
Mutator member functions are allowed to read data members, but not change them.		False	
Member functions that change the state of an object are called accessors.		False	
Accessor member functions should always end in the keyword const.	ı	True	
If your class does not have a constructor, the compiler will synthesize a working constructor for you.		False	
If a member function is in the private section of a class, it cannot be called from other member functions of the class.		False	
The implementation of a class normally appears entirely inside the class .cpp file.		False	
The implementation of a member function from the Time class would look something like this: int Time.hours() const {}.		False	
The interface of a class includes all items in the header file.		False	
The interface of a class includes all public items in the header file.		True	
When calling a member function, like thours(3); the address of the object t is passed to the function implicitly as the first parameter.		True	
Member functions that initialize the data members of a new object are called mutators.		False	
If you write a working constructor for your class, C++ will remove the synthesized default constructor.		True	
The implementation of a member function from the Time class would look something like this: int Time::hours() const {}		True	
With classes, the public interface includes the member functions that allow clients to access object data in a safe way.		True	
In C++ there is actually no difference between structures and classes.		False	
A class definition ends with a semicolon.		True	
The implementation of a class includes all private data members in the header file.	l	True	
In C++ you use the keyword public or private before each data member or member function to indicate its access privileges.		False	
In C++ there is actually no difference between structures and classes		False	
Mutator member functions are allowed to read data members, but not change them	Ī	False	
Programmers using class-derived objects, directly manipulate the data members of those objects.		False	
Using structures for user-defined types means that you cannot change the data representation without affecting the users of your data type.		True	
Using classes for user-defined types means that you cannot enforce restrictions on data member access.		False	

C-3·1		
Programmers using structure-derived variables, directly manipulate the data members of those variables.	Tru	ue
You may add = default; to the prototype for a default constructor to retain the synthesized version in the presence of other overloaded constructors.	Tru	ue
The implementation of a class normally appears partly inside the class .cpp file and partly inside the class .h file.	Tru	ue
If your class does not have a constructor, the compiler will synthesize a default constructor for you.	Tru	ue
If a member function is in the private section of a class, it can only be called by other member functions of the class.	Tru	ue
The implementation of a member function from the Time class would look something like this: int hours() const {}.	Fals	lse
The two parts of a class are a private interface and a public implementation.	Fals	lse
The public interface of a class consists of the prototypes of its member functions.	Tru	ue
Mutator member functions are allowed to read data members and also change them.	Tru	ue
A structure is an interface paired with an implementation.	Fals	lse
Using structures for user-defined types means that you can enforce restrictions on data member access.	Fals	lse
A class definition normally appears in a .h file.	Tru	ue
In C++ the only difference between structures and classes is that member functions are public by default in structures.	Tru	ue
Member functions that initialize the data members of a new object are called constructors.	Tru	ue
Using structures for user-defined types means that you can change the data representation without affecting the users of your data type.	Fals	lse
Accessor member functions are allowed to read data members, but not change them.	Tru	ue
The two parts of a class are a public interface and a private implementation.	Tru	ue
The member function int hours() const; provides read-only access to the hours property (however it is stored).	Tru	ue
In C++ the only difference between structures and classes is that member functions are private by default in classes.	Tru	ue
A constructor always has the same name as the class, and no return type.	Tru	ue
The member function int& hours(); provides read-write access to the hours property (however it is stored).	Tru	ue
Using structures for user-defined types means that you cannot enforce restrictions on data member access.	Tru	ue
Using classes for user-defined types means that you can change the data representation without affecting the users of your class.	Tru	ue
In C++ the only difference between structures and classes is that member functions are private by default in structures.	Fals	lse
A constructor that takes no arguments is called the working constructor.	Fals	lse

A class definition normally appears in a .cpp file	
The member function int& hours(); provides read-only access to the hours property (however it is stored)	
You may add = default; to the prototype of any constructor to allow the compiler to synthesize one for you	
The semicolon following a class definition is optional	
Member functions that initialize the data members of a new object are called accessors	
Using classes for user-defined types means that you cannot change the data representation without affecting the users of your class	
The keywords public and private are the C++ mechanism for defining interfaces and enforcing encapsulation	True
Member functions that change the state of an object are called mutators	
A constructor that takes no arguments is called the default constructor	
Using classes for user-defined types means that you can enforce restrictions on data member access	
Accessor member functions are allowed to read data members and also change them	
[2101] Which of these is not a property of an object (in the OOP sense)?	Substitutablility
Substitutablility Identity	
State	
All of these are properties of an object Behavior	
[2102] The of an object consist of its attributes or characteristics, represented by the values stored in its data members.	State

    A behavior of an object is represented by the messages that it responds to.
                                                                                           True
Using encapsulation such as that used with structures, risks accidental data
                                                                                            False
corruption.
Constructors always have the same name as the class, except that the constructor
                                                                                            False
name is capitalized.
In C++11 you can initialize members in the initializer list using braces, parentheses or
                                                                                            False
the assignment operator syntax.
                 Inheritance enforces the principle of data hiding.
                                                                                           False
          Constructors must be explicitly called after an object is created.
                                                                                            False
          Constructors are called implicitly whenever an object is created. \\
                                                                                           True
True
that those objects may be initialized twice.
The constructor that is used to initialize all of an object's fields is called the working
                                                                                            True
constructor.
  Constructors always have the same name as the class and a return type of void.
                                                                                            False
Initialization of data members occurs according to the order they are listed in the
                                                                                            True
```

The state of an object refers to the names and types of its data members.	False
With inheritance, the class you build upon is called a base class in C++.	True
With inheritance, the class you build upon is called a superclass in C++.	False
Suppose you have two classes related by inheritance: Dog and Poodle. According to the principle of substitutability, a function void walk(Poodle& p) will accept a Dog as an argument.	False
The state of an object refers to the combination of values stored in its data members.	True
Creating objects from a class is called instantiation.	True
If you do not create a constructor for your class, C++ will synthesize a working constructor for you.	False
The attributes of an object refers to the names and types of its data members.	True
If you do not create a constructor for your class, C++ will synthesize a default constructor for you.	True
A constructor is a member function whose job is to initialize an object into a well-formed state.	True
A constructor that takes a single argument of a different type is also known as a conversion constructor.	True
Polymorphism enforces the principle of data hiding.	False
A constructor that takes a single argument of a different type may be called implicitly.	True
Constructors always have the same name as the class and no return type.	True
A class specifies the behavior of the objects it creates through the definition of embedded functions, called member functions.	True
The constructor that is used to initialize all of an object's fields is called the default constructor.	False
With inheritance, the new class you create is called a base class in C++.	False
A function that is marked with the keyword inline should be placed in the implementation .cpp file.	False
Object behavior is implemented by data member.	False
Constructors always have the same name as the class, preceded by the tilde character (-).	False
A class represents a template or blueprint for creating objects of a particular kind.	True
Polymorphism only works in the presence of inheritance.	True
Your class may have more than one constructor.	True
Encapsulation enforces the principle of data hiding.	True
An object (in the OOP sense) is an instance of a particular class.	True
Object behavior is implemented by member functions.	True
A function that is marked with the keyword inline must be places in the header file.	True
C++11 you can ask the compiler to retain the synthesized constructor when adding new ones.	True
With inheritance, the class you build upon is called a derived class in C++.	False
The constructor that takes no arguments is called the working constructor.	False
Although not possible in earlier versions of C++, in C++11 you can ask the compiler to retain the synthesized constructor when adding new ones.	True
With inheritance, the new class you create is called a derived class in C++.	True
Objects are variables of programmer-defined types.	True
Marking a constructor with the explicit keyword, prevents unintended conversions.	True

With inheritance, the new class you create is called a subclass in C++.	<u> </u>	False
In a constructor, objects can be initialized immediately before the opening brace of the constructor, before any other code has been run.		True
In a constructor, objects can be initialized immediately after the opening brace of the constructor, before any other code has been run.		False
With inheritance, a family of related classes is called a class hierarchy.	I	True
A reference variable has the same identity as the variable it refers to.		True
The constructor that takes no arguments is called the default constructor.	<u> </u>	True
A reference variable has a different identity than the variable it refers to.	<u> </u>	False
Suppose you have two classes related by inheritance: Dog and Poodle. According to the rules of inheritance, Poodle is a specialization of Dog.		True
The constructor initializer list is preceded by a colon and followed by a semicolon.	<u> </u>	False
A class specifies the attributes of the objects it creates through the definition of internal data members.		True
Polymorphism means that different objects (of different types) can respond to the same message in different ways.		True
Suppose you have two classes related by inheritance: Dog and Poodle. According to the rules of inheritance, Dog is a specialization of Poodle.		False
With inheritance, the class you build upon is called a subclass in C++.	I	False
The attributes of an object refers to the combination of values stored in its data members.		False
The constructor initializer list follows the parameter list and precedes the constructor body.		True
Suppose you have two classes related by inheritance: Dog and Poodle. According to the principle of substitutability, a function void walk(Dog& d) will accept a Poodle as an argument.		False
When not using encapsulation, such with structures, you risk accidental data corruption.		True
Initialization of data members occurs according to the order they are listed in the initializer list.		False
To ask a particular object to perform a particular action, you send your request by calling a member function.		True
When not using encapsulation, such with structures, changing the implementation of the structure changes the interface as well.		True
With inheritance, the new class you create is called a superclass in C++.	I	False
A class specifies the attributes of the objects it creates through the definition of embedded functions, called member functions.		False
[2201] The BigNum class allows you to create arbitrarily large numbers, without any approximations. Assume you have the following code. What is the best header for the required operator?		const BigNum operator*(const BigNum& lhs, const BigNum& rhs);

};	
The parameter should be a non-constant reference	
The operator should have const at the end of the header	
The operator return type should be a Point&	
The operator should end with return this, not return *this	
Does not compile; should be a non-member function	
	ı

class Point { int x_{0}, y_{0}; public: Point(int x, int y): x_{x}, y_{y} {}; int x() const { return x_; } int y() const { return y_; } Point& operator+=(const Point& rhs) { } }; const Point operator+(Point& lhs, const Point& rhs) { return lhs += rhs; } The operator should not change any of its parameters There is no error; it works fine. Does not compile; should be a member function. The rhs parameter should not be const The operator should return lhs after adding rhs to it.	
[2230] The Point class represents x,y coordinates in a Cartesian plane. What is the mistake in this operator? (Members written inline for this problem.)	There is no error; it works fine.
<pre>class Point { int x_{0}, y_{0}; public: Point(int x, int y): x_{x}, y_{y} {} int x() const { return x_{j} } int y() const { return y_{j} } Point& operator+=(const Point& rhs) { } };</pre>	
const Point operator+(const Point& lhs, const Point& rhs) { return Point(lhs) += rhs; } The operator should not change any of its parameters The operator return type should be a Point&. The rhs parameter should not be const Does not compile; should be a member function. There is no error; it works fine.	
[2231] The Point class represents x,y coordinates in a Cartesian plane. What is the mistake in this operator? (Members written inline for this problem.)	The operator return type should not be a Point&.
<pre>class Point { int x_{0}, y_{0}; public: Point(int x, int y): x_{x}, y_{y} {} int x() const { return x_; } int y() const { return y_; } Point& operator+=(const Point& rhs) { } };</pre>	
Point& operator+(const Point& lhs, const Point& rhs) { return Point(lhs) += rhs; }	
There is no error; it works fine.	
Does not compile; should be a member function	
The rhs parameter should not be const	
The operator should not change any of its parameters	
The operator return type should not be a Point&.	

```
class Point {
int x_{0}, y_{0};
public:
 Point(int x, int y): x_{x}, y_{y} {}
 int x() const { return x_; }
 int y() const { return y_; }
ostream& operator<<(ostream& out, const Point& p)
return out << '(' << p.x() << ", " << p.y() << ')';
There is no error; it works fine
The Point p parameter should not be const
Does not compile; should be a member function
 You must return out after writing to it. This example returns void
 The data members x_{\underline{\ }} and y_{\underline{\ }} are inaccessible in a non-member function
                                                                                                                                                                                                                                                                                                                                            The data members x_{\underline{\ }} and y_{\underline{\ }} are inaccessible in a non-member function
[2233] The Point class represents x,y coordinates in a Cartesian plane. What is the
mistake in this operator? (Members written inline for this problem.)
class Point {
int x_{0}, y_{0};
public:
 Point(int x, int y): x_{x}, y_{y} {}
 int x() const { return x_; }
int y() const { return y_; }
};
ostream& operator<<(ostream& out, const Point& p)
return out << '(' << p.x_ << ", " << p.y_ << ')';
 The Point p parameter should not be const
Does not compile; should be a member function
 There is no error; it works fine.
 You must return out after writing to it. This example returns void % \left( 1\right) =\left( 1\right) \left( 1\right) 
 The data members x_{\underline{\ }} and y_{\underline{\ }} are inaccessible in a non-member function
[2234] The Point class represents x,y coordinates in a Cartesian plane. What is the
                                                                                                                                                                                                                                                                                                                                            You must return out after writing to it. This example returns void.
 mistake in this operator? (Members written inline for this problem.)
 class Point {
int x_{0}, y_{0};
public:
 Point(int x, int y): x_{x}, y_{y} {}
 int x() const { return x_; }
int y() const { return y_; }
  void operator<<(ostream& out, const Point& p)</pre>
  out << '(' << p.x() << ", " << p.y() << ')';
Does not compile; should be a member function.
The data members x_ and y_ are inaccessible in a non-member function.
The Point p parameter should not be const
 You must return out after writing to it. This example returns void.
 There is no error; it works fine.
```

```
class Point {
int x_{0}, y_{0};
public:
Point(int x, int y): x_{x}, y_{y} {}
int x() const { return x_; }
int y() const { return y_; }
ostream& operator<<(ostream& out, Point& p)
return out << '(' << p.x() << ", " << p.y() << ')';
The data members x_{\underline{\ }} and y_{\underline{\ }} are inaccessible in a non-member function.
There is no error; it works fine.
The Point p parameter should be const
Does not compile; should be a member function.
You must first write to out and then return it.
        The prototype for a member subtraction operator for the type T is:
                                                                                              False
        const T operator-(const T& lhs, const T& rhs);
        The prototype for a non-member addition operator for the type T is:
                                                                                              False
        const T operator+(const T& rhs) const;
       The prototype for a non-member subtraction operator for the type T is:
      const T operator-(const T& lhs, const T& rhs);
                    You may not overload the scope operator ::
                                                                                             True
 The parameter names lhs and rhs are commonly used with overloaded operators.
                                                                                             True
         Overloaded operators may be implemented as member functions.
                                                                                             True
         The expression *this can be returned from non-member operators.
                                                                                              False
        The short-hand assignment operators for type T should return *this.
                                                                                              True
         The expression *this can only be returned from member operators.
                                                                                             True
   With operator overloading, you may use any symbol to define a new operator.
                                                                                              False
You must use the ordinary meaning of an operator when you overload it. It would be
                                                                                              False
impossible to redefine subtraction to mean addition, for instance.
          The prototype for a member addition operator for the type T is:
                                                                                              True
          const T operator+(const T& rhs) const;
              To compare objects for equality, overload both == and !=.
                                                                                             True
Though not required, you should use the ordinary meaning of an operator when you
                                                                                              True
overload it. It would be unwise to redefine subtraction to mean addition, for
instance.
Overloaded operators are functions that use special names that begin with the
                                                                                              False
The arithmetic operators, such as addition, subtraction and multiplication for type \mathsf{T}
should return a const T.
           The signature for the postfix decrement operator (of type T) is:
                                                                                              False
           T& operator--();
                                                                                              False
                   You may overload the conditional operator ?:.
                    The expression *this is called a self-reference.
                                                                                             True
        Classes whose objects need to be sorted should overload == and !=.
                                                                                              True
      You can only overload existing operators. You cannot use other symbols.
                                                                                              True
           The signature for the postfix decrement operator (of type T) is:
                                                                                              True
           const T operator--(int);
           The subscript operators must be written as a member operator.
                                                                                             True
                 You may overload operators for the built-in types.
                                                                                             False
```

	1
The I/O operators must always be written as non-member operators.	True
Symetric operators, where the user-defined type may appear on the left or the right, should be written as member operators.	False
The short-hand assignment operators for type T should return a T&.	True
Side-effect operators, such as increment or short-hand assignment, should be written as member operators.	True
The signature for the prefix increment operator (of type T) is:	False
const T operator++(int);	
You may not overload the subscript ([]) operator.	False
Symetric operators, where the user-defined type may appear on the left or the right, should be written as non-member operators.	True
The arithmetic operators, such as addition, subtraction and multiplication for type T should return a T.	False
Overloaded operators may be implemented as non-member functions.	True
An overloaded operator must have at least one operand that is a user-defined type.	True
The short-hand assignment operators for type T should return a const T.	False
Member operators have direct access to private data members.	True
The I/O operators should always be written as member operators.	False
You may not overload the conditional operator ?:.	True
The parameter names left and right are commonly used with overloaded operators.	False
Classes whose objects need to be sorted should overload <.	False
The subscript operators may be written as a member operator or as a non-member operator.	False
Side-effect operators, such as increment or short-hand assignment, should be written as non-member operators.	False
Non-member operators have direct access to private data members.	True
The arithmetic operators, such as addition, subtraction and multiplication for type T should return a T&.	False
You may not overload the indirection operator, the unary *.	False

[2330] Which of the following statements is correct about a recursive function?
                                                                                                A recursive function calls itself.
A recursive function must never call another function.
A recursive function calls itself.
A recursive function must be simple.
A recursive function must call another function.
                [2331] What does this function do?
                                                                                                Prints the string word in reverse
                void myfun(string word)
                if (word.length() == 0) return;
                my fun (word.substr(1, word.length())); \\
                cout << word[0];
                }
                Prints the length of the string word
                Prints the string word both forward and reverse
                Prints the string word in reverse
                Prints the string word
                                                                                                reverses the order in which the characters of the string are printed
    [2332] What changes about this function if lines 4 and 5 are swapped?
    1. void myfun(string word)
    2. {
    3. if (word.length() == 0) { return; }
     4. myfun(word.substr(1, word.length()));
     5. cout << word[0];
     prints the characters of the string in both forward and reverse order
     creates infinite recursion
    nothing
    reverses the order in which the characters of the string are printed
```

Recursion always helps you create a more efficient solution than other techniques.	
A recursion eventually exhausts all available memory, causing the program to terminate	
A recursive computation solves a problem by calling itself with simpler input.	
None of the listed options.	
[2334] How can you ensure that a recursive function terminates?	Provide a special case for the simplest inputs
Call the recursive function with simpler inputs. Use more than one return statement. Provide a special case for the simplest inputs. Provide a special case for the most complex inputs.	
[2335] Which of the following is a key requirement to ensure that recursion is successful?	Every recursive call must simplify the computation in some way.
Every recursive call must simplify the computation in some way	
A recursive solution should not be implemented to a problem that can be solved iteratively	
There should be special cases to handle the most complex computations directly	
A recursive function should not call itself except for the simplest inputs	
[2336] What is the value of r(3)?	6
int r(int n) {	
if (n < 2) { return 1; } return n * r(n - 1);	
}	
24 2	
120 6	
[2337] Which statement ensures that r() terminates for all values of n?	if (n < 1) { return 1; }
int mr(int n)	
{ // code goes here	
return r(n - 1) + n * n; }	
if (n == 1) { return 1; } if (n == 0) { return 0; }	
if (n == 0) { return 0; }	
if (n < 1) { return 1; }	
if (n == 1) { return 1; }	
[2338] Infinite recursion can lead to an error known as	stack overflow
stack overflow	
heap exhaustion	
heap fragmentation memory exception	
[2339] Infinite recursion can occur because	the base case is missing one of the necessary termination conditions
the base case is missing one of the necessary termination conditions	
the recursive function is called more than once the recursive case is invoked with simpler arguments a second function is called from the recursive one	
[2340] Two quantities a and b are said to be in the golden ratio if mc040-1,jpg is equal to mc040-2,jpg. Assuming a and b are line segments, the golden section is a line segment divided according to the golden ratio: The total length (a + b) is to the longer segment a as a is to the shorter segment b. One way to calculate the golden ratio is through the continued square root (also called an infinite surd): golden ratio = mc040-3,jpg. In a recursive implementation of this function, what should be the base case for the recursion? if (number <= 1) { return pow(number, 2.0);} if (number <= 1) { return sqrt(number);} if (number <= 1) { return 0.0;}	if (number <= 1) { return 1.0;}

segment divided according to the golden ratio: The total length (a + b) is to the longer segment a as a is to the shorter segment b. One way to calculate the golden ratio is through the continued square root (also called an infinite surd): golden ratio If the function double golden (int) is a recursive implementation of this function, what should be the recursive call in that function? return sqrt (1.0 + golden(number)); return sqrt (1.0 + golden(number - 1)); return (1.0 + golden(number - 1)); return (1.0 + golden(number));	
[2342] In 1735 Leonard Euler proved a remarkable result, which was the solution to the Basel Problem, first posed in 1644 by Pietro Mengoli. This result gave a simple expression for mc042-1,jpg. The formula states that mc042-2,jpgis equal to the limit, as n goes to infinity, of the series mc042-3,jpg. Can this series be computed recursively? Yes, but the code will be very long No, because the base case is not zero Yes No, because there is no base case	Yes
[2343] In 1735 Leonard Euler proved a remarkable result, which was the solution to the Basel Problem, first posed in 1644 by Pietro Mengoli. This result gave a simple expression The formula states that equal to the limit, as n goes to infinity, of the series Which function below is a correct recursive implementation that approximates this infinite series?	<pre>double computePI(int number) { if (number <= 1) { return 1.0;} return 1.0 / (number * number) + computePI(number - 1); }</pre>
[2344] In 1735 Leonard Euler proved a remarkable result, which was the solution to the Basel Problem, first posed in 1644 by Pietro Mengoli. This result gave a simple expression for mc044-1.jpg. The formula states that mc044-2.jpgis equal to the limit, as n goes to infinity, of the series mc044-3.jpg. Which statement below is the correct base case for a recursive implementation that approximates this infinite series?	if (number <= 1) { return 1.0;}
<pre>if (number == 0) { return 1.0 / (number * number);} if (number <= 1) { return 1.0;} if (number <= 1) { return 0.0;} if (number == 1) { return (number * number);}</pre>	
[2345] In 1735 Leonard Euler proved a remarkable result, which was the solution to the Basel Problem, first posed in 1644 by Pietro Mengoli. This result gave a simple expression for mc045-1,jpg. The formula states that mc045-2,jpgis equal to the limit, as n goes to infinity, of the series mc045-3,jpg. Which statement below is the recursive case for a recursive implementation that approximates this infinite series? return 1.0 / (number * number) + computePI(number - 1); return 1.0 + computePI(number);	return 1.0 / (number * number) + computePI(number - 1);
return 1.0 + computePI(number - 1); return 1.0 / (number * number) + computePI(number);	
[2346] One remarkably simple formula for calculating the value of is the so-called Madhava-Leibniz series: Consider the recursive function below to calculate this formula:	When the parameter variable is less than or equal to one
<pre>double computePI(int number) { if (number <= 1) { return 1.0;} int oddnum = 2 * number - 1; return computesign(number) * 1.0 / oddnum + computePI(number - 1); }</pre>	
In this recursive function, what is the recursive base case? When the parameter variable is less than or equal to one When the parameter variable is greater than one When the value that is returned from the function is zero When the parameter variable is zero	

recursive function below to calculate this formula:	
double computePI(int number)	
<pre>if (number <= 1) { return 1.0;} int oddnum = 2 * number - 1; return computesign(number) * 1.0 / oddnum + computePI(number - 1); }</pre>	
In this recursive function, what is the role of the helper function computesign?	
it is the recursive call in the function	
it checks the sign of the number and returns true if it is positive and false if negative	
it is called just one time to set the sign of the final result	
it makes sure the sign (positive or negative) alternates as each term of the series is computed	
[2348] Assuming that you need to write a recursive function calc_prod(int n) to calculate the product of the first n integers, which of the following would be a correct way to simplify the input for the recursive call? Call calc_prod(n - 1) and multiply by n. Call calc_prod(n + 1) and multiply by n. Call calc_prod(n - 2) and multiply by n. Call calc_prod(1) and multiply by n.	Call calc_prod(n - 1) and multiply by n.
[2349] Suppose you need to write a recursive function power(double x , int n) that calculates x to the power of n . Which of the following would be a correct way to implement the function power? Call power(x , n) and multiply by (n - 1). Call power(x , n - 1) and multiply by n .	Call power(x, n - 1) and multiply by x.
Call power(x - 1, n) and multiply by x. Call power(x, n - 1) and multiply by x.	
[2501] Below is a class hierarchy for card games. Which of the Hand member functions may be overridden in the GoFishHand class?	score()
class Hand { std::vector <card> cards; public: void add(const Card&); Card get(size_t index) const; virtual int score() const;</card>	
class PokerHand : public Hand { }; class BlackjackHand : public Hand { }; class GoFishHand : public Hand { };	
get()	
add()	
score()	
all of them	
none of them	
[2502] Below is a class hierarchy for card games. Which is the correct signature for a function that can print the score of any playing card hand?	void printScore(const Hand* h);
class Hand { std::vector <card> cards; public: void add(const Card&); Card get(size_t index) const; virtual int score() const; };</card>	
class PokerHand : public Hand $\{\dots\}$; class BlackjackHand : public Hand $\{\dots\}$; class GoFishHand : public Hand $\{\dots\}$;	
void printScore(Hand h);	
void printScore(const Hand h);	
void printScore(const Hand* h);	
void printScore(BlackjackHand& h);	
void printScore(const PokerHand& h);	

	•
class Hand {	
std::vector <card> cards;</card>	
public:	
void add(const Card&);	
Card get(size_t index) const; virtual int score() const;	
);	
μ	
class PokerHand : public Hand { };	
class BlackjackHand : public Hand { };	
class GoFishHand : public Hand { };	
void showScore(const Hand h 🍁) {	
cout << h.score() << endl;	
}	
PokerHand ph;	
showScore(ph 🍇); // what happens here?	
The PokerHand portion of ph is sliced off and it becomes a Hand object	
It does not compile because ph is not a Hand object so we have a type error	
It does not compile because you should pass &ph instead of ph	
The Hand object is converted to a PokerHand object implicitly	
It prints the easys for the Deligal land ships transport to	
It prints the score for the PokerHand object named ph	
	I
[2504] Below is a class hierarchy for card games. What happens when showScore() is	It calls the PokerHand::score() function if one has been defined
called?

[2540] Which member function(s) in Hobbit cause a compiler error?	name(), print()	
<pre>class Creature { public: Creature(const string& name); virtual string name() const final; virtual string skills() const; virtual void addSkill(const string& skill); void print() const; };</pre>		
class Hobbit : public Creature { public: string name() const override; string skills() const override; void addSkill(const string&) override; void print() override;		
};		
None of them		
name(), print()		
skills(), name(), print()		
addSkill(), skills(), name()		
Tell the compiler that you intend to override a base class function by adding the keyword override as an annotation before the function header	False	
Putting the keyword final at the end of a non-virtual member function heading prohibits derived classes from overriding that function		
Virtual functions invoked through an object use late binding to decide which function to call		
The composition relationship is informally known as is-a		
Virtual member functions are implemented by adding a new pointer, called a vtable, to every object that contains at least one virtual function		
If you make a class final then you must make all of its member functions final as well		
In private inheritance derived classes inherit the interface of the base class, but not its implementation		
The public inheritance relationship is informally known as implemented-with		
If a derived class redefine a non-virtual base-class function it causes a syntax error		
The public inheritance relationship is informally known as has-a		
Non-virtual functions always use late binding to decide which function to call		
Waiting until runtime to determine which function to call is known as early binding		

The public inheritance relationship is informally known as is-a	
The composition relationship is informally known as has-a	
The keyword override allows the compiler to ensure that the base-class function you are overriding is virtual	
Non-virtual functions always use early, or compile-time binding to decide which function to call	
Creating a new class by combining instances of simpler classes as data members is called composition	
It is always a logic error for a derived class to redefine a non-virtual function	
Putting the keyword final at the end of the class heading prohibits the creation of subsequent derived classes	
Waiting until runtime to determine which function to call is known as late binding	
Waiting until runtime to determine which function to call is known as dynamic dispatch	
Virtual functions invoked through a pointer to a base-class object use late binding to decide which function to call	
If a virtual member function does not use the keyword final, then any derived class may override that function	
In private inheritance derived classes inherit the implementation of the base class, but not its interface	
Virtual functions invoked through a reference to a base-class object use late binding to decide which function to call	
Virtual member functions are implemented by adding a new pointer to every object that contains at least one virtual function	
In private inheritance a using declaration is employed to selectively bring base class members into the derived class scope	
Tell the compiler that you intend to override a base class function by adding the keyword override to the end of the member function declaration	
Putting the keyword final at the end of a virtual member function heading prohibits derived classes from overriding that function	
[2401] is one of the primary mechanisms that we use to understand the natural world around us. Starting as infants we begin to recognize the difference between categories like food, toys, pets, and people. As we mature, we learn to divide these general categories or classes into subcategories like siblings and parents, vegetables and dessert	classification

derived from Question. Which of the following is true?	
NumericQuestion contains a numerical answer but not a query	
NumericQuestion contains a query and a numerical answer but no answer string	
It is impossible to know without examining the definition of the NumericQuestion class	
NumericQuestions contains both a query and an answer string.	
[2423] Which one of the following is an example of the "substitution principle"?	A derived class object can be used in place of a base-class object.
A base-class object must be used in place of a derived class object	
A base-class object can be used in place of a derived class object	
A derived class object must be used in place of a base-class object	
A derived class object can be used in place of a base-class object	
[2424] Suppose that we have a function that registers a Vehicle object. We also have a Car object that is a specialized Vehicle (defined by inheritance). The substitution principle states	The Car object can be used in the Vehicle registration function because it is a kind of Vehicle.
The Car object can never be used in any function that is written to use a Vehicle object.	
A new registration function that is written to use a Car object can be used in place of the Vehicle registration function	
The Car object can be used in the Vehicle registration function because it is a kind of Vehicle	
The Vehicle object can always be used wherever a Car object is expected	
[2425] The Department of Motor Vehicles uses a vehicle registration program that declares a Vehicle class as a base class. The Car class and the Truck class both inherit from the Vehicle class. Which types of objects can be passed to the function register(Vehicle& v)?	Vehicle, Car and Truck objects
It is impossible to know without examining the implementation of the Car and Truck classes	
Vehicle, Car and Truck objects	
Only Car and Truck objects	
Only Vehicle objects	
[2426] Consider the following classes. The Vehicle class is a base class. The Car, Truck, and Motorcycle class inherit from the Vehicle class. The Sedan and SUV classes inherit from the Car class. Which of the following lists all the types of objects that cannot be passed into the function calculate_registration_fee(Car& car)?	Motorcycle, Truck, and Vehicle objects
Motorcycle, Truck, and Vehicle objects	
Motorcycle, and Truck objects	
Sedan and SUV objects	
Sedan, SUV, and Car objects	
[2427] How can a derived class override a base class function?	By providing a new implementation for a function with the same name and parameter types

Nothing is required in the derived class - this is automatically provided by $% \left\{ \left(1\right) \right\} =\left\{ \left($

It is impossible for the derived class to override a base class function

By providing a new implementation for a function with the same name and $% \left(1\right) =\left(1\right) \left(1\right) \left($

By providing a new implementation for a function, tagged with the override reserved $% \left(x\right) =\left(x\right) +\left(x\right)$

inheritance

setAriswer()	

-	
class Car { public: Car(); virtual void setSpeed(double); double getSpeed() const; void display() const; }; class AeroCar : public Car { public: AeroCar(); void setSpeed(double); void setSpeed(double); double getHeight(double); double getHeight() const; };	
Neither A nor B	
car.getSpeed() and aero.getSpeed()	
car.getHeight() and aero.getHeight()	
Both A and B	
[2433] Based on the following declaration of the Employee class where Manager is derived from Employee, which of the following are true?	The Manager class inherits name and salary, but Manager functions can only change the values of the name data member
class Employee { public: Employee(); Employee(const string&); Employee(double); Employee(const string&, double); void setName(const string&); string getName()const; private: string name; double salary; };	
The Manager class does not inherit the private data members	
The Manager class inherits name and salary, but Manager functions can only change the values of the name data member	
A Manager object has direct access to the name and salary inherited data members	
The Manager class inherits name and salary, but Manager functions cannot change the values of either data member.	
[2434] The Car class inherits from the Vehicle class. The Car class contains one constructor which does not call a particular Vehicle constructor. Which of the following is true?	The Vehicle default constructor is implicitly called by the Car constructor
Vehicle constructors can never be called by the Car constructors	
The Car class will not compile because it does not explicitly call a Vehicle constructor	
The Vehicle default constructor is implicitly called by the Car constructor	
All Vehicle constructors are implicitly called by the Car constructor.	
[2435] The Manager class is derived from the Employee class. Manager defines a constructor, but does not explicitly call an Employee constructor. Which constructor is called by the Manager constructor?	Employee();
class Employee { public: Employee(); Employee(const string&); Employee(double); Employee(const string&, double); };	
Employee(const string&, double);	
Employee();	
Employee(const string&);	
Employee(double);	

```
AeroCar acar1(2000.0, 200.0);

In C++, as in Java pure virtual member functions may not have an implementation	False	
The C++ facility that allows a derived class to have multiple base classes is known as interface inheritance		
In C++, an Abstract Base Class is any class that has one or more virtual member functions		
The istream class in the C++ standard library uses multiple inheritance		
Since an abstract class cannot be instantiated, it is illegal to have references of abstract types		
Using public inheritance to derive Stack from vector is a good design because vector provides all of the capabilities that a Stack requires		
An abstract class is a class that contains no data members		
Constructing an instance of an abstract class is legal, provided you do not initialize it		
Consider the Shape class hierarchy, along with Circle, Square and Star from your text. The Shape class is a concrete class		
What Java calls a static method is called a pure virtual member function in C++		
If a class is abstract, you may create instances, but not pointers of that class		
An abstract class may, but is not required to, override its pure virtual (abstract) member functions		
Composition models an IS-A relationship between classes		
Composition can be used to create adapter classes that change the implementation of one class to meet the needs of another		
Private inheritance models an IS-A relationship between classes		
In C++, public inheritance can be used to create adapter classes		
An abstract class is a class that contains only virtual member functions		
Using the keyword abstract to the heading of a virtual member function converts it to a pure virtual member function		
Abstract classes provide a set of capabilities that derived classes my inherit		
In adapter classes, the member functions override superclass member functions to provide new behavior		
Consider the Shape class hierarchy, along with Circle, Square and Star from your text. The Circle class is an abstract class		

It is illegal to construct an instance of an abstract class Abstract classes specify a set of responsibilities that derived classes must fulfill The iostream class in the C++ standard library uses multiple inheritance In C++, an Abstract Base Class is any class that has one pure virtual member function An abstract class is a class that contains member functions that are specified but not implemented The C++ facility that allows a derived class to have multiple base classes is known as multiple inheritance In C++ pure virtual member functions may have an optional implementation Adding = 0 to the end of the heading of a virtual member function converts it to a pure virtual member function An abstract class requires its concrete derived classes to override all of its pure virtual (abstract) member functions In composition-based adapter classes, the member functions delegate or forward requests to the data member that can satisfy the request In C++, private inheritance can be used to create adapter classes Public inheritance models an IS-A relationship between classes $\,$ Using public inheritance to derive Stack from vector is a problem because a Stack is really not a vector If a class is abstract, you may create a pointer of that class What Java calls an abstract method is called a pure virtual member function in C++ Consider the Shape class hierarchy, along with Circle, Square and Star from your text. The Shape class is an abstract base class [1213] What is stored in data after this runs? vector<int> data{1, 2, 3}; data.back(); [1,2,3] None of these [1, 2, 3, 0] [2, 3] [1, 2] [1, 2, 3] [1540] What is printed?
